

High Efficiency Synchronous Step-Down Switching Regulator

May 1999

FEATURES

- Dual N-Channel MOSFET Synchronous Drive
- **Programmable/Synchronizable Fixed Frequency**
- V_{OUT} Range: 0.8V to 7V
- Wide V_{IN} Range: 3.5V to 36V Operation
- Very Low Dropout Operation: 99% Duty Cycle
- **OPTI-LOOP™ Compensation Minimizes C_{OUT}**
- **$\pm 1\%$ Output Voltage Accuracy**
- **Power Good Output Voltage Monitor**
- Internal Current Foldback
- Output Overvoltage Crowbar Protection
- Latched Short-Circuit Shutdown Timer with Defeat Option
- Optional Programmable Soft-Start
- Remote Output Voltage Sense
- Logic Controlled Micropower Shutdown: $I_Q < 25\mu A$
- Available in 16-Lead Narrow SSOP and SO Packages

APPLICATIONS

- Notebook and Palmtop Computers, PDAs
- Power Supply for Mobile Pentium® III Processor
- Cellular Telephones and Wireless Modems

Burst Mode and OPTI-LOOP are trademarks of Linear Technology Corporation.
Pentium is a registered trademark of Intel Corporation.

DESCRIPTION

The LTC®1735-1 is a synchronous step-down switching regulator controller optimized for CPU power. OPTI-LOOP compensation allows the transient response to be optimized over a wide range of output capacitance and ESR values.

The operating frequency (synchronizable up to 500kHz) is set by an external capacitor allowing maximum flexibility in optimizing efficiency. The output voltage is monitored by a power good window comparator that indicates when the output is within 7.5% of its programmed value, conforming to Intel Mobile CPU Specifications.

Protection features include internal foldback current limiting, output overvoltage crowbar and optional short-circuit shutdown. Soft-start is provided by an external capacitor that can be used to properly sequence supplies. The operating current level is user-programmable via an external current sense resistor. Wide input supply range allows operation from 3.5V to 30V (36V maximum).

Pin defeatable Burst Mode™ operation provides high efficiency at low load currents while 99% duty cycle provides low dropout operation.

TYPICAL APPLICATION

Note 1: Absolute Maximum Ratings are those values beyond which the life of a device may be impaired.

Note 2: T_J is calculated from the ambient temperature T_A and power dissipation P_D according to the following formulas:

$$\text{LTC1735CS-1, LTC1735IS-1: } T_J = T_A + (P_D \cdot 110^\circ\text{C/W})$$

$$\text{LTC1735CGN-1, LTC1735IGN-1: } T_J = T_A + (P_D \cdot 140^\circ\text{C/W})$$

Note 3: The LTC1735-1 is tested in a feedback loop that servos V_{OSENSE} to the balance point for the error amplifier ($V_{ITH} = 1.2\text{V}$).

Note 4: The minimum on-time condition corresponds to an inductor peak-to-peak ripple current $> 40\%$ of I_{MAX} (see Minimum On-Time Considerations in the Applications Information section).

Note 5: Dynamic supply current is higher due to the gate charge being delivered at the switching frequency. See Applications Information.

Note 6: Oscillator frequency is tested by measuring the C_{OSC} charge current (I_{OSC}) and applying the formula:

$$f_{OSC} (\text{kHz}) = \left(\frac{8.477(10^8)}{C_{OSC}(\text{pF}) + 11} \right) \left(\frac{1}{I_{CHG}} + \frac{1}{I_{DIS}} \right)^{-1}$$

PIN FUNCTIONS

C_{OSC} (Pin 1): External capacitor C_{OSC} from this pin to ground sets the operating frequency.

RUN/SS (Pin 2): Combination of Soft-Start and Run Control Inputs. A capacitor to ground at this pin sets the ramp time to full current output. The time is approximately 0.5s/μF. Forcing this pin below 1.3V causes the device to be shut down. In shutdown all functions are disabled. Latchoff overcurrent protection is also invoked via this pin as described in the Applications Information section.

I_{TH} (Pin 3): Error Amplifier Compensation Point. The current comparator threshold increases with this control voltage. Nominal voltage range for this pin is 0V to 2.4V.

PGOOD (Pin 4): Open-Drain Logic Output and Forced Continuous/Synchronization Input. The PGOOD pin is pulled to ground when the voltage on the V_{OSENSE} pin is not within ±7.5% of its nominal set point. If power good indication is not needed, this pin can be tied to ground to force continuous synchronous operation. Clocking this pin with a signal above 1.5V_{P-P} synchronizes the internal oscillator to the external clock. Synchronization only occurs while the main output is in regulation (PGOOD not internally pulled low). When synchronized, Burst Mode operation is disabled but cycle skipping is allowed at low load currents. This pin requires a pull-up resistor for power good indication. Do not connect this pin directly to an external source (or INTV_{CC}). Do not exceed INTV_{CC} on this pin.

SENSE⁻ (Pin 5): The (–) Input to the Current Comparator.

SENSE⁺ (Pin 6): The (+) Input to the Current Comparator. Built-in offsets between SENSE⁺ and SENSE⁻ pins in conjunction with R_{SENSE} set the inductor current trip threshold.

V_{OSENSE} (Pin 7): Receives the feedback voltage from an external resistive divider across the output.

SGND (Pin 8): Small-Signal Ground. This pin must be routed separately from other grounds to the (–) terminal of C_{OUT}.

EXTV_{CC} (Pin 9): Input to the Internal Switch Connected to INTV_{CC}. This switch closes and supplies V_{CC} power whenever EXTV_{CC} is higher than 4.7V. See EXTV_{CC} connection in Applications Information section. Do not exceed 7V on this pin and ensure EXTV_{CC} is ≤ V_{IN}.

PGND (Pin 10): Driver Power Ground. This pin connects to the source of the bottom N-channel MOSFET, the anode of the Schottky diode and the (–) terminal of C_{IN}.

BG (Pin 11): High Current Gate Drive for the Bottom N-Channel MOSFET. Voltage swing at this pin is from ground to INTV_{CC}.

INTV_{CC} (Pin 12): Output of the Internal 5.2V Low Dropout Regulator and EXTV_{CC} Switch. The driver and control circuits are powered from this voltage. Must be closely decoupled to power ground with a minimum of 4.7μF tantalum or other low ESR capacitor.

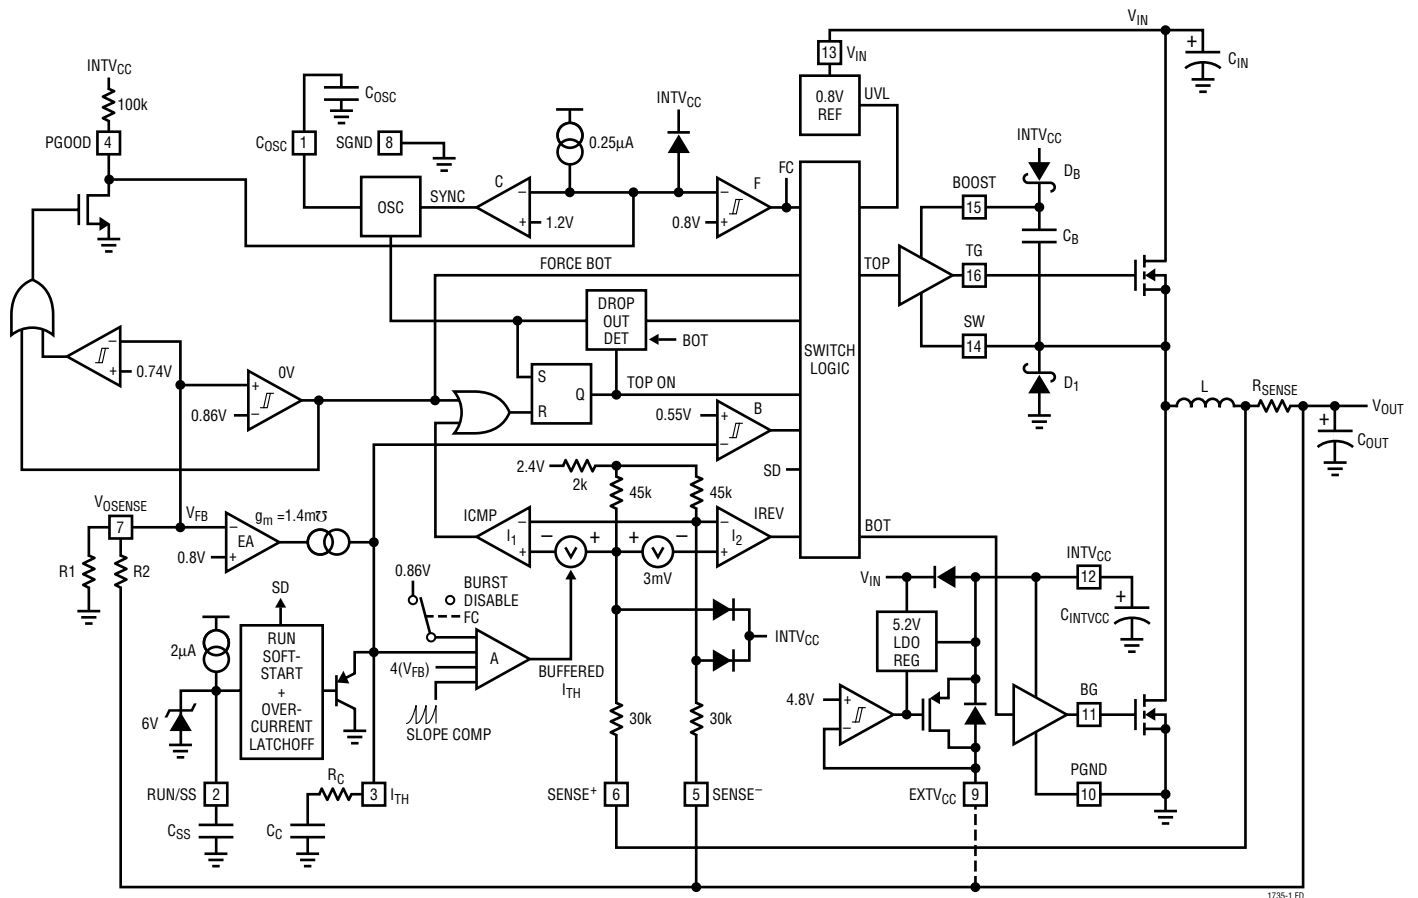

V_{IN} (Pin 13): Main Supply Pin. This pin must be closely decoupled to power ground.

SW (Pin 14): Switch Node Connection to Inductor and Bootstrap Capacitor. Voltage swing at this pin is from a Schottky diode (external) voltage drop below ground to V_{IN}.

BOOST (Pin 15): Supply to Topside Floating Driver. The bootstrap capacitor is returned to this pin. Voltage swing at this pin is from a diode drop below INTV_{CC} to V_{IN} + INTV_{CC}.

TG (Pin 16): High Current Gate Drive for Top N-Channel MOSFET. This is the output of a floating driver with a voltage swing equal to INTV_{CC} superimposed on the switch node voltage SW.

FUNCTIONAL DIAGRAM

OPERATION (Refer to Functional Diagram)

Main Control Loop:

The LTC1735-1 uses a constant frequency, current mode step-down architecture. During normal operation, the top MOSFET is turned on each cycle when the oscillator sets the RS latch, and turned off when the main current comparator I_1 resets the RS latch. The peak inductor current at which I_1 resets the RS latch is controlled by the voltage on Pin I_{TH} , which is the output of error amplifier EA. Pin V_{OSENSE} , described in the Pin Functions, allows EA to receive an output feedback voltage V_{OSENSE} from the external resistive divider. When the load current increases, it causes a slight decrease in V_{OSENSE} relative to the 0.8V reference, which in turn causes the I_{TH} voltage to increase

until the average inductor current matches the new load current. While the top MOSFET is off, the bottom MOSFET is turned on until either the inductor current starts to reverse, as indicated by current comparator I_2 , or the beginning of the next cycle.

The top MOSFET driver is powered from a floating bootstrap capacitor C_B . This capacitor is normally recharged from $INTV_{CC}$ through an external diode when the top MOSFET is turned off. As V_{IN} decreases towards V_{OUT} , the converter will attempt to turn on the top MOSFET continuously (“dropout”). A dropout counter detects this condition and forces the top MOSFET to turn off for about 500ns every tenth cycle to recharge the bootstrap capacitor.

OPERATION (Refer to Functional Diagram)

The main control loop is shut down by pulling Pin 2 (RUN/SS) low. Releasing RUN/SS allows an internal $2\mu\text{A}$ current source to charge soft-start capacitor C_{SS} . When C_{SS} reaches 1.3V, the main control loop is enabled with the I_{TH} voltage clamped at approximately 30% of its maximum value. As C_{SS} continues to charge, I_{TH} is gradually released allowing normal operation to resume. If V_{OUT} has not reached 70% of its final value when C_{SS} has charged to 4.1V, latching can be invoked as described in the Applications Information section.

The internal oscillator can be synchronized to an external clock applied through a series resistor to the PGOOD pin and can lock to a frequency between 90% and 130% of its nominal rate set by capacitor C_{OSC} .

An overvoltage comparator OV guards against transient overshoots ($>7.5\%$) and other mild conditions that may overvoltage the output. In this case, the top MOSFET is turned off and the bottom MOSFET is turned on until the overvoltage condition is cleared.

Foldback current limiting for an output shorted to ground is provided by amplifier A. As V_{OSENSE} drops below 0.6V, the buffered I_{TH} input to the current comparator is gradually pulled down to a 0.86V clamp. This reduces peak inductor current to about 1/4 of its maximum value.

Low Current Operation

The LTC1735-1 has three low current modes controlled by the PGOOD control pin. Burst Mode operation is selected when the PGOOD pin voltage is above 0.8V (typically tied through a resistor to $INTV_{CC}$). During Burst Mode operation, if the error amplifier drives the I_{TH} voltage below 0.86V, the buffered I_{TH} input to the current comparator will be clamped at 0.86V. The inductor current peak is then held at approximately $20\text{mV}/R_{SENSE}$ (about 1/4 of maximum output current). If I_{TH} then drops below 0.5V, the Burst Mode comparator B will turn off both MOSFETs to maximize efficiency. The load current will be supplied solely by the output capacitor until I_{TH} rises above the 50mV hysteresis of the comparator and switching is resumed. Burst Mode operation is disabled by comparator

F when the PGOOD pin is brought below 0.8V. This forces continuous operation and assists in controlling voltage regulation. If the output voltage is not within 7.5% of its nominal value the PGOOD open-drain output will be pulled low and Burst Mode operation will be disabled.

Foldback Current, Short-Circuit Detection and Short-Circuit Latchoff

The RUN/SS capacitor, C_{SS} , is used initially to limit the inrush current of the switching regulator. After the controller has been started and been given adequate time to charge up the output capacitors and provide full load current, C_{SS} is used as a short-circuit time-out circuit. If the output voltage falls to less than 70% of its nominal output voltage, C_{SS} begins discharging on the assumption that the output is in an overcurrent and/or short-circuit condition. If the condition lasts for a long enough period, as determined by the size of the C_{SS} , the controller will be shut down until the RUN/SS pin voltage is recycled. This built-in latchoff can be overridden by providing a $>5\mu\text{A}$ pull-up at a compliance of 4V to the RUN/SS pin. This current shortens the soft-start period but also prevents net discharge of C_{SS} during an overcurrent and/or short-circuit condition. Foldback current limiting is activated when the output voltage falls below 70% of its nominal level whether or not the short-circuit latchoff circuit is enabled.

$INTV_{CC}/EXTV_{CC}$ Power

Power for the top and bottom MOSFET drivers and most of the internal circuitry of the LTC1735-1 is derived from the $INTV_{CC}$ pin. When the $EXTV_{CC}$ pin is left open, an internal 5.2V low dropout regulator supplies the $INTV_{CC}$ power from V_{IN} . If $EXTV_{CC}$ is raised above 4.7V, the internal regulator is turned off and an internal switch connects $EXTV_{CC}$ to $INTV_{CC}$. This allows a high efficiency source, such as the primary or a secondary output of the converter itself, to provide the $INTV_{CC}$ power.

To provide clean start-up and to protect the MOSFETs, undervoltage lockout is used to keep both MOSFETs off until the input voltage is above 3.5V.

OPERATION (Refer to Functional Diagram)

POWER GOOD

A window comparator monitors the output voltage and its open-drain output is pulled low when the divided down output voltage (appearing at the V_{OSENSE} pin) is not within $\pm 7.5\%$ of the reference voltage of 0.8V.

During a programmed output voltage transition (i.e., a transition from 1.55V to 1.3V) the PGOOD open-drain output will be pulled low and Burst Mode operation will be disabled until the output voltage is within 7.5% of its newly programmed value.

When the PGOOD pin is driven by an external oscillator through a series resistor, cycle-skipping operation is invoked and the internal oscillator is synchronized to the external clock by comparator C. In this mode, the 25% minimum inductor current clamp is removed, providing low noise, constant frequency discontinuous operation

over the widest possible output current range. This constant frequency operation is not quite as efficient as Burst Mode operation, but does provide a lower noise, constant frequency operation. When the power good window comparator indicates the output is not in regulation, the PGOOD pin is pulled to ground and synchronization is inhibited. Obviously when driving the PGOOD pin with an external clock the power good indication is not available unless additional circuitry is added.

If the PGOOD pin is tied to ground, continuous operation is forced. This operation is the least efficient mode, but is desirable in certain applications. The output can source or sink current in this mode. When forcing continuous operation and sinking current, current will be forced back into the main power supply potentially boosting the input supply to dangerous voltage levels—BEWARE.

APPLICATIONS INFORMATION

The basic LTC1735-1 application circuit is shown in Figure 1 on the first page of this data sheet. External component selection is driven by the load requirement, and begins with the selection of R_{SENSE} . Once R_{SENSE} is known, C_{OSC} and L can be chosen. Next, the power MOSFETs and D1 are selected. The operating frequency and the inductor are chosen based largely on the desired amount of ripple current. Finally, C_{IN} is selected for its ability to handle the large RMS current into the converter and C_{OUT} is chosen with low enough ESR to meet the output voltage ripple specification. The circuit shown in Figure 1 can be configured for operation up to an input voltage of 28V (limited by the external MOSFETs).

R_{SENSE} Selection For Output Current

R_{SENSE} is chosen based on the required output current. The LTC1735-1 current comparator has a maximum threshold of $75\text{mV}/R_{SENSE}$ and an input common mode range of SGND to $1.5(\text{INTV}_{CC})$. The current comparator threshold sets the peak of the inductor current, yielding a maximum average output current I_{MAX} equal to the peak value less half the peak-to-peak ripple current, ΔI_L .

Allowing a margin for variations in the LTC1735-1 and external component values yields:

$$R_{SENSE} = \frac{50\text{mV}}{I_{MAX}}$$

C_{OSC} Selection for Operating Frequency and Synchronization

The choice of operating frequency and inductor value is a trade-off between efficiency and component size. Low frequency operation improves efficiency by reducing MOSFET switching losses, both gate charge loss and transition loss. However, lower frequency operation requires more inductance for a given amount of ripple current.

The LTC1735-1 uses a constant frequency architecture with the frequency determined by an external oscillator capacitor C_{OSC} . Each time the topside MOSFET turns on, the voltage C_{OSC} is reset to ground, after which C_{OSC} is charged by a fixed current. When the voltage on the capacitor reaches 1.19V, C_{OSC} is reset to ground. The process then repeats.

APPLICATIONS INFORMATION

The value of C_{OSC} is calculated from the desired operating frequency assuming no external clock input on the PGOOD pin:

$$C_{OSC}(\text{pF}) = \left[\frac{1.61(10^7)}{\text{Frequency}} \right] - 11$$

A graph for selecting C_{OSC} versus frequency is given in Figure 2. The maximum recommended switching frequency is 550kHz.

The internal oscillator runs at its nominal frequency (f_0) when the PGOOD pin is pulled high (to INTV_{CC}) through a series resistor or connected to ground. Clocking the PGOOD pin above and below 1.2V will cause the internal oscillator to injection-lock to an external clock signal applied to the PGOOD pin with a frequency between $0.9f_0$ and $1.3f_0$. The clock high level must exceed 1.3V for at least $0.3\mu\text{s}$, and the clock low level must be less than 0.3V for at least $0.3\mu\text{s}$. The top MOSFET turn-on will synchronize with the rising edge of the external clock.

Attempting to synchronize to too high of an external frequency (above $1.3f_0$) can result in inadequate slope compensation and possible loop instability at high duty cycles. If this condition exists, simply lower the value of C_{OSC} so ($f_{EXT} = f_0$) according to Figure 2.

Figure 2. Timing Capacitor Value

When synchronized to an external clock, Burst Mode operation is disabled but the inductor current is not allowed to reverse. The 25% minimum inductor current

clamp present in Burst Mode operation is removed, providing constant frequency discontinuous operation over the widest possible output current range. In this mode the synchronous MOSFET is forced on once every ten clock cycles to recharge the bootstrap cap. This minimizes audible noise while maintaining reasonably high efficiencies.

Inductor Value Calculation

The operating frequency and inductor selection are inter-related in that higher operating frequencies allow the use of smaller inductor and capacitor values. So why would anyone ever choose to operate at lower frequencies with larger components? The answer is efficiency. A higher frequency generally results in lower efficiency because of MOSFET gate charge losses. In addition to this basic trade off, the effect of inductor value on ripple current and low current operation must also be considered.

The inductor value has a direct effect on ripple current. The inductor ripple current ΔI_L decreases with higher inductance or frequency and increases with higher V_{IN} or V_{OUT} :

$$\Delta I_L = \frac{1}{(f)(L)} V_{OUT} \left[1 - \frac{V_{OUT}}{V_{IN}} \right]$$

Accepting larger values of ΔI_L allows the use of low inductances, but results in higher output voltage ripple and greater core losses. A reasonable starting point for setting ripple current is $\Delta I_L = 0.4(I_{MAX})$. Remember, the maximum ΔI_L occurs at the maximum input voltage.

The inductor value also has an effect on low current operation. The transition to low current operation begins when the inductor current reaches zero while the bottom MOSFET is on. Lower inductor values (higher ΔI_L) will cause this to occur at higher load currents, which can cause a dip in efficiency in the upper range of low current operation. In Burst Mode operation, lower inductance values will cause the burst frequency to decrease.

Inductor Core Selection

Once the value for L is known, the type of inductor must be selected. High efficiency converters generally cannot afford the core loss found in low cost powdered iron cores,

APPLICATIONS INFORMATION

forcing the use of more expensive ferrite, molypermalloy, or Kool M μ ® cores. Actual core loss is independent of core size for a fixed inductor value, but it is very dependent on inductance selected. As inductance increases, core losses go down. Unfortunately, increased inductance requires more turns of wire and therefore copper losses will increase.

Ferrite designs have very low core loss and are preferred at high switching frequencies, so design goals can concentrate on copper loss and preventing saturation. Ferrite core material saturates “hard,” which means that inductance collapses abruptly when the peak design current is exceeded. This results in an abrupt increase in inductor ripple current and consequent output voltage ripple. Do not allow the core to saturate!

Molypermalloy (from Magnetics, Inc.) is a very good, low loss core material for toroids, but it is more expensive than ferrite. A reasonable compromise from the same manufacturer is Kool M μ . Toroids are very space efficient, especially when you can use several layers of wire. Because they generally lack a bobbin, mounting is more difficult. However, designs for surface mount are available that do not increase the height significantly.

Power MOSFET and D1 Selection

Two external power MOSFETs must be selected for use with the LTC1735-1: an N-channel MOSFET for the top (main) switch, and an N-channel MOSFET for the bottom (synchronous) switch.

The peak-to-peak gate drive levels are set by the INTV_{CC} voltage. This voltage is typically 5.2V during start-up (see EXT_{VCC} Pin Connection). Consequently, logic-level threshold MOSFETs must be used in most LTC1735-1 applications. The only exception is when low input voltage is expected ($V_{IN} < 5V$); then, sub-logic level threshold MOSFETs ($V_{GS(TH)} < 3V$) should be used. Pay close attention to the BV_{DSS} specification for the MOSFETs as well; most of the logic level MOSFETs are limited to 30V or less.

Selection criteria for the power MOSFETs include the “ON” resistance $R_{DS(ON)}$, reverse transfer capacitance C_{RSS} , input voltage and maximum output current. When the LTC1735-1 is operating in continuous mode the duty cycles for the top and bottom MOSFETs are given by:

$$\text{Main Switch Duty Cycle} = \frac{V_{OUT}}{V_{IN}}$$

$$\text{Synchronous Switch Duty Cycle} = \frac{V_{IN} - V_{OUT}}{V_{IN}}$$

The MOSFET power dissipations at maximum output current are given by:

$$P_{MAIN} = \frac{V_{OUT}}{V_{IN}} (I_{MAX})^2 (1 + \delta) R_{DS(ON)} + k(V_{IN})^2 (I_{MAX}) (C_{RSS}) (f)$$

$$P_{SYNC} = \frac{V_{IN} - V_{OUT}}{V_{IN}} (I_{MAX})^2 (1 + \delta) R_{DS(ON)}$$

where δ is the temperature dependency of $R_{DS(ON)}$ and k is a constant inversely related to the gate drive current.

Both MOSFETs have I^2R losses while the topside N-channel equation includes an additional term for transition losses, which are highest at high input voltages. For $V_{IN} < 20V$ the high current efficiency generally improves with larger MOSFETs, while for $V_{IN} > 20V$ the transition losses rapidly increase to the point that the use of a higher $R_{DS(ON)}$ device with lower C_{RSS} actually provides higher efficiency. The synchronous MOSFET losses are greatest at high input voltage or during a short circuit when the duty cycle in this switch is nearly 100%.

The term $(1 + \delta)$ is generally given for a MOSFET in the form of a normalized $R_{DS(ON)}$ vs Temperature curve, but $\delta = 0.005/^\circ C$ can be used as an approximation for low voltage MOSFETs. C_{RSS} is usually specified in the MOSFET characteristics. The constant $k = 1.7$ can be used to estimate the contributions of the two terms in the main switch dissipation equation.

The Schottky diode D1 shown in Figure 1 conducts during the dead-time between the conduction of the two large power MOSFETs. This prevents the body diode of the bottom MOSFET from turning on and storing charge during the dead-time, which could cost as much as 1% in efficiency. A 3A Schottky is generally a good size for 10A to 12A regulators. The diode may be omitted if the efficiency

Kool M μ is a registered trademark of Magnetics, Inc.

APPLICATIONS INFORMATION

can be tolerated. Larger diodes result in additional transition losses due to their larger junction capacitance.

C_{IN} and C_{OUT} Selection

In continuous mode, the source current of the top N-channel MOSFET is a square wave of duty cycle V_{OUT}/V_{IN} . To prevent large voltage transients, a low ESR input capacitor sized for the maximum RMS current must be used. The maximum RMS capacitor current is given by:

$$I_{RMS} \cong I_{O(MAX)} \frac{V_{OUT}}{V_{IN}} \left(\frac{V_{IN}}{V_{OUT}} - 1 \right)^{1/2}$$

This formula has a maximum at $V_{IN} = 2V_{OUT}$, where $I_{RMS} = I_{OUT}/2$. This simple worst-case condition is commonly used for design because even significant deviations do not offer much relief. Note that capacitor manufacturer's ripple current ratings are often based on only 2000 hours of life. This makes it advisable to further derate the capacitor, or to choose a capacitor rated at a higher temperature than required. Several capacitors may also be paralleled to meet size or height requirements in the design. Always consult the manufacturer if there is any question.

The selection of C_{OUT} is primarily determined by the effective series resistance (ESR) to minimize voltage ripple. The output ripple (ΔV_{OUT}) is determined by:

$$\Delta V_{OUT} \approx \Delta I_L \left(ESR + \frac{1}{4fC_{OUT}} \right)$$

where f = operating frequency, C_{OUT} = output capacitance, and ΔI_L = ripple current in the inductor. The output ripple is highest at maximum input voltage since ΔI_L increases with input voltage. Typically, once the ESR requirement for C_{OUT} has been met, the RMS current rating generally far exceeds the $I_{RIPPLE(P-P)}$ requirement. With $\Delta I_L = 0.3I_{OUT(MAX)}$ and allowing for 2/3 of the ripple due to ESR, the output ripple will be less than 50mV at max V_{IN} assuming:

$$C_{OUT} \text{ required } ESR < 2.2 R_{SENSE}$$

$$C_{OUT} > 1/(8fR_{SENSE})$$

The first condition relates to the ripple current into the ESR of the output capacitor while the second term guarantees

that the output voltage does not significantly discharge during the operating frequency period due to ripple current. The choice of using smaller output capacitance increases the ripple voltage due to the discharging term but can be compensated for by using capacitors of very low ESR to maintain the ripple voltage at or below 50mV. The I_{TH} pin OPTI-LOOP compensation components can be optimized to provide stable, high performance transient response regardless of the output capacitors selected.

Manufacturers such as Nichicon, United Chemicon and Sanyo can be considered for high performance through-hole capacitors. The OS-CON semiconductor dielectric capacitor available from Sanyo has the lowest (ESR)(size) product of any aluminum electrolytic at a somewhat higher price. An additional ceramic capacitor in parallel with OS-CON capacitors is recommended to reduce the inductance effects.

In surface mount applications, multiple capacitors may need to be used in parallel to meet the ESR, RMS current handling and load step requirements of the application. Aluminum electrolytic, dry tantalum and special polymer capacitors are available in surface mount packages. Special polymer surface mount capacitors offer very low ESR but have much lower capacitive density per unit volume than other capacitor types. These capacitors offer a very cost-effective output capacitor solution and are an ideal choice when combined with a controller having high loop bandwidth. Tantalum capacitors offer the highest capacitance density and are often used as output capacitors for switching regulators having controlled soft-start. Several excellent surge-tested choices are the AVX TPS, AVX TPSV or the KEMET T510 series of surface mount tantalums, available in case heights ranging from 2mm to 4mm. Aluminum electrolytic capacitors can be used in cost-driven applications providing that consideration is given to ripple current ratings, temperature and long-term reliability. A typical application will require several to many aluminum electrolytic capacitors in parallel. A combination of the above mentioned capacitors will often result in maximizing performance and minimizing overall cost. Other capacitor types include Sanyo OS-CON, Nichicon PL series and Sprague 595D series. Consult manufacturers for other specific recommendations.

APPLICATIONS INFORMATION

INTV_{CC} Regulator

An internal P-channel low dropout regulator produces the 5.2V supply that powers the drivers and internal circuitry within the LTC1735-1. The INTV_{CC} pin can supply up to 50mA and must be bypassed to ground with a minimum of 4.7μF tantalum, 10μF special polymer or low ESR type electrolytic capacitor. Good bypassing is required to supply the high transient currents required by the MOSFET gate drivers.

Higher input voltage applications in which large MOSFETs are being driven at high frequencies may cause the maximum junction temperature rating for the LTC1735-1 to be exceeded. The supply current is dominated by the gate charge supply current. Additional loading of INTV_{CC} also needs to be taken into account for the power dissipation calculations. The total INTV_{CC} current can be supplied by either the 5.2V internal regulator or the EXTV_{CC} pin. When the voltage applied to the EXTV_{CC} pin is less than 4.7V, all of the INTV_{CC} current is supplied by the internal 5.2V linear regulator. Power dissipation for the IC in this case is the highest, $(V_{IN})(I_{INTVCC})$, and overall efficiency is lowered. The gate charge current is dependant on operating frequency as discussed in the Efficiency Consideration section. The junction temperature can be estimated by using the equations given in Note 2 of the Electrical Characteristics. For example, the LTC1735CS-1 is limited to less than 17mA from a 30V supply:

$$T_J = 70^{\circ}\text{C} + (17\text{mA})(30\text{V})(110^{\circ}\text{C}/\text{W}) = 126^{\circ}\text{C}$$

Use of the EXTV_{CC} input pin reduces the junction temperature to:

$$T_J = 70^{\circ}\text{C} + (17\text{mA})(5\text{V})(110^{\circ}\text{C}/\text{W}) = 79^{\circ}\text{C}$$

To prevent maximum junction temperature from being exceeded, the input supply current must be checked operating in continuous mode at maximum V_{IN} .

EXTV_{CC} Connection

The LTC1735-1 contains an internal P-channel MOSFET switch connected between the EXTV_{CC} and INTV_{CC} pins. Whenever the EXTV_{CC} pin is above 4.7V the internal 5.2V

regulator shuts off, the switch closes, and INTV_{CC} power is supplied via EXTV_{CC} until EXTV_{CC} drops below 4.5V. This allows the MOSFET gate drive and control power to be derived from the output or other external source during normal operation. When the output is out of regulation (start-up, short circuit) power is supplied from the internal regulator. Do not apply greater than 7V to the EXTV_{CC} pin and ensure that $\text{EXTV}_{\text{CC}} \leq V_{\text{IN}}$.

Significant efficiency gains can be realized by powering INTV_{CC} from the output, since the V_{IN} current resulting from the driver and control currents will be scaled by a factor of (Duty Cycle)/(Efficiency). For 5V regulators this simply means connecting the EXTV_{CC} pin directly to V_{OUT} . However, for dynamic VID programmed regulators and other lower voltage regulators, additional circuitry is required to derive INTV_{CC} power from the output.

The following list summarizes the three possible connections for EXTV_{CC}:

1. EXTV_{CC} Left Open (or Grounded). This will cause INTV_{CC} to be powered from the internal 5.2V regulator resulting in an efficiency penalty of up to 10% at high input voltages.
2. EXTV_{CC} Connected to an External Supply (This Option is the Most Likely Used). If an external supply is available in the 5V to 7V range, such as notebook main 5V system power, it may be used to power EXTV_{CC} providing it is compatible with the MOSFET gate drive requirements. This is the typical case as the 5V power is almost always present and is derived by another high efficiency regulator.
3. EXTV_{CC} Connected to an Output-Derived Boost Network. For low output voltage regulators, efficiency gains can still be realized by connecting EXTV_{CC} to an output-derived voltage that has been boosted to greater than 4.7V. This can be done with either the inductive boost winding or capacitive charge pump circuits. Refer to the LTC1735 data sheet for details. The charge pump has the advantage of simple magnetics.

APPLICATIONS INFORMATION

Output Voltage Programming

The output voltage is set by an external resistive divider according to the following formula:

$$V_{OUT} = 0.8V \left(1 + \frac{R2}{R1} \right)$$

The resistive divider is connected to the output as shown in Figure 3 allowing remote voltage sensing.

Figure 3. Setting the LTC1735-1 Output Voltage

The output voltage can be digitally set to voltages between any two levels with the addition of a resistor and small signal N-channel MOSFET as shown in the circuit of Figure 1. Dynamic output voltage selection can be accomplished with this technique. Output voltages of 1.30V and 1.55V are set by the resistors R1 to R3. With the gate of the MOSFET low, ($V_G = 0$), the output voltage is set by the ratio of R1 to R2. When the MOSFET is on ($V_G = \text{high}$), the output voltage is the ratio of R1 to the parallel combination of R2 and R3. With the available power good output (PGOOD), the circuit in Figure 1 creates a low cost Intel Pentium III mobile processor compliant supply.

The LTC1735-1 has remote sense capability. The top of the internal resistive divider is connected to V_{OSENSE} and is referenced to the SGND pin. This allows a kelvin connection for remotely sensing the output voltage directly across the load, eliminating any PC board trace resistance errors.

Topside MOSFET Driver Supply (C_B , D_B)

An external bootstrap capacitor C_B connected to the BOOST pin supplies the gate drive voltage for the topside MOSFET. Capacitor C_B in the Functional Diagram is charged though external diode D_B from $INTV_{CC}$ when the SW pin is low. Note that the voltage across C_B is about a diode drop

below $INTV_{CC}$. When the topside MOSFET is to be turned on, the driver places the C_B voltage across the gate-source of the MOSFET. This enhances the MOSFET and turns on the topside switch. The switch node voltage SW rises to V_{IN} and the BOOST pin rises to $V_{IN} + INTV_{CC}$. The value of the boost capacitor C_B needs to be 100 times greater than the total input capacitance of the topside MOSFET. In most applications 0.1 μ F to 0.33 μ F is adequate. The reverse breakdown on D_B must be greater than $V_{IN(\text{MAX})}$.

When adjusting the gate drive level, the final arbiter is the total input current for the regulator. If you make a change and the input current decreases, then you improved the efficiency. If there is no change in input current, then there is no change in efficiency.

SENSE+ / SENSE- Pins

The common mode input range of the current comparator is from 0V to 1.5($INTV_{CC}$). Continuous linear operation is guaranteed throughout this range allowing output voltages anywhere from 0.8V to 7V. A differential NPN input stage is used and is biased with internal resistors from an internal 2.4V source as shown in the Functional Diagram. This causes current either to be sourced or sunk by these pins depending on the output voltage. If the output voltage is below 2.4V, current will flow out of both SENSE pins to the main output. This forces a minimum load current that can be fulfilled by the V_{OUT} resistive divider resistors R1 and R2. The maximum current flowing out of the SENSE pins is:

$$I_{SENSE^+} + I_{SENSE^-} = (2.4V - V_{OUT})/24k$$

Since V_{OSENSE} is servoed to the 0.8V reference voltage, we can choose R1 in Figure 3 to have a maximum value to absorb this current:

$$R1(\text{Max}) = 24k \left(\frac{0.8V}{2.4V - V_{OUT}} \right)$$

Regulating an output voltage of 1.8V, the maximum value of R1 should be 32k. Note that for output voltages above 2.4V no maximum value of R1 is necessary to absorb the sense currents; however, R1 is still bounded by the V_{OSENSE} feedback current.

APPLICATIONS INFORMATION

Soft-Start/Run Function

The RUN/SS pin is a multipurpose pin that provides a soft-start function and a means to shut down the LTC1735-1. Soft-start reduces surge currents from V_{IN} by gradually increasing the controller's current limit $I_{TH(MAX)}$. This pin can also be used for power supply sequencing.

Pulling the RUN/SS pin below 1.3V puts the LTC1735-1 into a low quiescent current shutdown ($I_Q < 25\mu A$). This pin can be driven directly from logic as shown in Figures 4 and 5. Releasing the RUN/SS pin allows an internal $2\mu A$ current source to charge up the external RUN/SS capacitor C_{SS} . If RUN/SS has been pulled all the way to ground there is a delay before starting of approximately:

$$T_{DELAY} = \frac{1.3V}{2\mu A} C_{SS} = (650ms/\mu F) C_{SS}$$

When the voltage on RUN/SS reaches 1.3V the LTC1735-1 begins operating with a current limit at approximately $25mV/R_{SENSE}$. As the voltage on RUN/SS increases from 1.3V to 3V, the internal current limit is increased from $25mV/R_{SENSE}$ to $75mV/R_{SENSE}$. The output current limit ramps up slowly, taking an additional $850ms/\mu F$ to reach full current. Ramping the output current slowly reduces the starting surge current required from the input supply.

Figure 4. RUN/SS Pin Interfacing

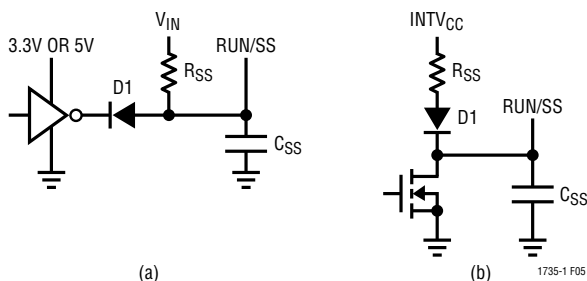

Figure 5. RUN/SS Pin Interfacing with Latchoff Defeated

Diodes D1 in Figure 4 and Figure 5 reduce the start delay while allowing C_{SS} to charge up slowly for the soft-start function. This diode and C_{SS} can be deleted if soft-start is not needed. The RUN/SS pin has an internal 6V zener clamp (see Functional Diagram).

Fault Conditions: Overcurrent Latchoff

The RUN/SS pin also provides the ability to shut off the controller and latchoff when an overcurrent condition is detected. The RUN/SS capacitor C_{SS} is used initially to turn on and limit the inrush current of the controller. After the controller has been started and given adequate time to charge up the output capacitor and provide full load current, C_{SS} is used as a short-circuit timer. If the output voltage falls to less than 70% of its nominal output voltage *after* C_{SS} reaches 4.1V, the assumption is made that the output is in a severe overcurrent and/or short-circuit condition and C_{SS} begins discharging. If the condition lasts for a long enough period as determined by the size of C_{SS} , the controller will be shut down until the RUN/SS pin voltage is recycled.

This built-in latchoff can be overridden by providing a current $> 5\mu A$ at a compliance of 4V to the RUN/SS pin as shown in Figure 5a. This current shortens the soft-start period but also prevents net discharge of the RUN/SS capacitor during a severe overcurrent and/or short-circuit conditions. When deriving the $5\mu A$ current from V_{IN} as in Figure 5a, current latchoff is always defeated. The diode connecting this pull-up resistor to $INTV_{CC}$, as in Figure 5b, eliminates any extra supply current during shutdown while eliminating the $INTV_{CC}$ loading from preventing the controller from starting up.

Why should you defeat current latchoff? During the prototyping stage of a design, there may be a problem with noise pickup or poor layout causing the protection circuit to latch off. Defeating this feature will easily allow troubleshooting of the circuit and PC layout. The internal short circuit and foldback current limiting still remains active, thereby protecting the power supply system from failure. After the design is complete, a decision can be made whether to rely solely on foldback current limiting or to enable the latchoff feature.

APPLICATIONS INFORMATION

The value of the soft-start capacitor C_{SS} will need to be scaled with output voltage, output capacitance and load current characteristics. The minimum soft-start capacitance is given by:

$$C_{SS} > (C_{OUT})(V_{OUT})(10^{-4})(R_{SENSE})$$

The minimum recommended soft-start capacitor of $C_{SS} = 0.1\mu\text{F}$ will be sufficient for most applications.

Fault Conditions: Current Limit and Current Foldback

The LTC1735-1 current comparator has a maximum sense voltage of 75mV resulting in a maximum MOSFET current of $75\text{mV}/R_{SENSE}$.

The LTC1735-1 includes current foldback to help further limit load current when the output is shorted to ground. If the output falls by more than half, then the maximum sense voltage is progressively lowered from 75mV to 30mV. Under short-circuit conditions with very low duty cycles, the LTC1735-1 will begin cycle skipping in order to limit the short-circuit current. In this situation the bottom MOSFET will be conducting the peak current. The short-circuit ripple current is determined by the minimum on-time $t_{ON(MIN)}$ of the LTC1735-1 (less than 200ns), the input voltage, and inductor value:

$$\Delta I_{L(SC)} = t_{ON(MIN)}(V_{IN}/L)$$

The resulting short circuit-current is:

$$I_{SC} = \frac{30\text{mV}}{R_{SENSE}} + \frac{1}{2}\Delta I_{L(SC)}$$

The current foldback function is always active and is not effected by the current latchoff function.

Fault Conditions: Output Overvoltage Protection (Crowbar)

The output overvoltage crowbar is designed to blow a system fuse in the input lead when the output of the regulator rises much higher than nominal levels. This condition causes huge currents to flow, much greater than in normal operation. This feature is designed to protect against a shorted top MOSFET; it does not protect against a failure of the controller itself.

The comparator (OV in the Functional Diagram) detects overvoltage faults greater than 7.5% above the nominal output voltage. When this condition is sensed the top MOSFET is turned off and the bottom MOSFET is forced on. The bottom MOSFET remains on continuously for as long as the OV condition persists; if V_{OUT} returns to a safe level, normal operation automatically resumes. Note that dynamically changing the output voltage may cause overvoltage protection to be momentarily activated during output voltage decreases. This will not cause permanent latchoff nor will it disrupt the desired voltage change.

With soft-latch overvoltage protection, dynamically changing the output voltage is allowed and the overvoltage protection tracks the newly programmed output voltage, always protecting the load (CPU).

Minimum On-Time Considerations

Minimum on-time $t_{ON(MIN)}$ is the smallest amount of time that the LTC1735-1 is capable of turning the top MOSFET on and off again. It is determined by internal timing delays and the gate charge required to turn on the top MOSFET. Low duty cycle applications may approach this minimum on-time limit and care should be taken to ensure that:

$$t_{ON(MIN)} < \frac{V_{OUT}}{V_{IN}(f)}$$

If the duty cycle falls below what can be accommodated by the minimum on-time, the LTC1735-1 will begin to skip cycles. The output voltage will continue to be regulated, but the ripple voltage and current will increase.

The minimum on-time for the LTC1735-1 in a properly configured application is less than 200ns. However, as the peak sense voltage decreases, the minimum on-time gradually increases. This is of particular concern in forced continuous applications with low ripple current at light loads. If the duty cycle drops below the minimum on-time limit in this situation, a significant amount of cycle skipping can occur with correspondingly larger current and voltage ripple.

If an application can operate close to the minimum on-time limit, an inductor must be chosen that is low enough

APPLICATIONS INFORMATION

to provide sufficient ripple amplitude to meet the minimum on-time requirement. *As a general rule keep the inductor ripple current equal or greater than 30% of $I_{OUT(MAX)}$ at $V_{IN(MAX)}$.*

PGOOD Pin Operation

The PGOOD pin is a multifunction pin intended primarily to indicate when the output voltage is within $\pm 7.5\%$ of its nominal set point. A window comparator monitors the V_{OSENSE} pin and activates an open-drain internal MOSFET that pulls down the PGOOD pin when the output voltage is out of regulation. Normally a 10k to 100k pull-up resistor is connected to this pin from a voltage source such as $INTV_{CC}$. Do not apply a voltage greater than $INTV_{CC}$ to this pin. Dynamically changing the output voltage between two voltage levels greater than 7.5% apart from each other will invoke the power good indication, causing the PGOOD output to go low until the new output voltage is reached.

When the DC voltage on the PGOOD pin drops below its 0.8V threshold, continuous mode operation is forced. In this case, the top and bottom MOSFETs continue to be driven synchronously regardless of the load on the main output. Burst Mode operation is disabled and current reversal is allowed in the inductor. This mode is forced whenever the output voltage is not within its 7.5% window.

In addition to providing a power good output, the PGOOD pin provides a logic input to force continuous synchronous operation and allow synchronization to an external clock.

The internal LTC1735-1 oscillator can be synchronized to an external oscillator by applying a clock signal to the PGOOD pin through a series resistor with a signal amplitude above $1.5V_{P-P}$. When synchronized to an external frequency, Burst Mode operation is disabled but cycle skipping is allowed at low load currents since current reversal is inhibited. The bottom gate will come on every 10 clock cycles to assure the bootstrap capacitor is kept refreshed. The rising edge of an external clock applied to the PGOOD pin starts a new cycle. If the output voltage is not within the 7.5% window around its nominal set point, the open-drain PGOOD output will pull low, disabling the external synchronization.

The following table summarizes the possible states available on the PGOOD pin.

Table 1

PGOOD PIN	CONDITION
DC Voltage: 0V to 0.7V	No Power Good Indication Burst Mode Operation Disabled/Forced Continuous Current Reversal Enabled
Resistor Pull-Up to $INTV_{CC}$ (or Other DC Voltage Less Than $INTV_{CC}$)	Power Good Indication Burst Mode, No Current Reversal When Power is Good
Resistor to Ext Clock: (0V to 1.5V)	No Power Good Indication Burst Mode Operation Disabled No Current Reversal

The circuit shown in Figure 6 provides a power good output and forces continuous operation. Transistor Q1 keeps the voltage at the PGOOD pin below 0.8V thus disabling Burst Mode operation. When the window comparator indicates the output voltage is within its 7.5% window, the base of Q1 is pulled to ground and the power good output appearing at the collector of Q2 goes low.

Figure 6. Forced Continuous Operation with Power Good Indication

Efficiency Considerations

The percent efficiency of a switching regulator is equal to the output power divided by the input power times 100%. It is often useful to analyze individual losses to determine what is limiting the efficiency and which change would produce the most improvement. Percent efficiency can be expressed as:

$$\% \text{Efficiency} = 100\% - (L1 + L2 + L3 + \dots)$$

where L1, L2, etc., are the individual losses as a percentage of input power.

APPLICATIONS INFORMATION

Although all dissipative elements in the circuit produce losses, four main sources usually account for most of the losses in LTC1735-1 circuits: 1) LTC1735-1 V_{IN} current, 2) $INTV_{CC}$ current, 3) I^2R losses, 4) Topside MOSFET transition losses.

1. The V_{IN} current is the DC supply current given in the electrical characteristics which excludes MOSFET driver and control currents. V_{IN} current results in a small (<0.1%) loss that increases with V_{IN} .
2. $INTV_{CC}$ current is the sum of the MOSFET driver and control currents. The MOSFET driver current results from switching the gate capacitance of the power MOSFETs. Each time a MOSFET gate is switched from low to high to low again, a packet of charge dQ moves from $INTV_{CC}$ to ground. The resulting dQ/dt is a current out of $INTV_{CC}$ that is typically much larger than the control circuit current. In continuous mode, $I_{GATECHG} = f(Q_T + Q_B)$, where Q_T and Q_B are the gate charges of the topside and bottom-side MOSFETs.

By powering $EXTV_{CC}$ from an output-derived source (or other high efficiency source), the additional V_{IN} current resulting from the driver and control currents will be scaled by a factor of (Duty Cycle)/(Efficiency). For example, in a 15V to 1.8V application, 10mA of $INTV_{CC}$ current results in approximately 1.2mA of V_{IN} current. This reduces the midcurrent loss from 10% or more (if the driver was powered directly from V_{IN}) to only a few percent.

3. I^2R losses are predicted from the DC resistances of the MOSFET, inductor and current shunt. In continuous mode, the average output current flows through L and R_{SENSE} , but is “chopped” between the topside main MOSFET and the synchronous MOSFET. If the two MOSFETs have approximately the same $R_{DS(ON)}$, then the resistance of one MOSFET can simply be summed with the resistances of L and R_{SENSE} to obtain I^2R losses. For example, if each $R_{DS(ON)} = 0.02\Omega$, $R_L = 0.03\Omega$, and $R_{SENSE} = 0.01\Omega$, then the total resistance is 0.06Ω . This results in losses ranging from 3% to 17% as the output current increases from 1A to 5A for a 1.8V output, or 4% to 20% for a 1.5V output. Efficiency varies as the inverse square of V_{OUT} for the same

external components and power level. I^2R losses cause the efficiency to drop at high output currents.

4. Transition losses apply only to the topside MOSFET(s), and only when operating at high input voltages (typically 20V or greater). Transition losses can be estimated from:

$$\text{Transition Loss} = (1.7) V_{IN}^2 I_{O(MAX)} C_{RSS} f$$

Other “hidden” losses such as copper trace and internal battery resistances can account for an additional 5% to 10% efficiency degradation in portable systems. It is very important to include these “system” level losses in the design of a system. The internal battery and fuse resistance losses can be minimized by making sure that C_{IN} has adequate charge storage and a very low ESR at the switching frequency. A 25W supply will typically require a minimum of 20 μ F to 40 μ F of capacitance having a maximum of 0.01 Ω to 0.02 Ω of ESR. Other losses including Schottky conduction losses during dead-time and inductor core losses generally account for less than 2% total additional loss.

Checking Transient Response

The regulator loop response can be checked by looking at the load current transient response. Switching regulators take several cycles to respond to a step in DC (resistive) load current. When a load step occurs, V_{OUT} shifts by an amount equal to ΔI_{LOAD} (ESR), where ESR is the effective series resistance of C_{OUT} . ΔI_{LOAD} also begins to charge or discharge C_{OUT} generating the feedback error signal that forces the regulator to adapt to the current change and return V_{OUT} to its steady-state value. During this recovery time V_{OUT} can be monitored for excessive overshoot or ringing, which would indicate a stability problem. OPTI-LOOP compensation allows the transient response to be optimized over a wide range of output capacitance and ESR values. The availability of the I_{TH} pin not only allows optimization of control loop behavior but also provides a DC coupled and AC filtered closed-loop response test point. The DC step, rise time and settling at this test point truly reflects the closed loop response. Assuming a predominantly second order system, phase margin and/or damping factor can be estimated using the percentage of

APPLICATIONS INFORMATION

overshoot seen at this pin. The bandwidth can also be estimated by examining the rise time at the pin. The I_{TH} external components shown in the Figure 1 circuit will provide an adequate starting point for most applications.

The I_{TH} series R_C - C_C filter sets the dominant pole-zero loop compensation. The values can be modified slightly (from 0.5 to 2 times their suggested values) to maximize transient response once the final PC layout is done and the particular output capacitor type and value have been determined. The output capacitors need to be decided upon because the various types and values determine the loop feedback factor gain and phase. An output current pulse of 20% to 100% of full load current having a rise time of $1\mu\text{s}$ to $10\mu\text{s}$ will produce output voltage and I_{TH} pin waveforms that will give a sense of the overall loop stability without breaking the feedback loop. The initial output voltage step may not be within the bandwidth of the feedback loop, so the standard second order overshoot/DC ratio cannot be used to determine phase margin. The gain of the loop will be increased by increasing R_C and the bandwidth of the loop will be increased by decreasing C_C . If R_C is increased by the same factor that C_C is decreased, the zero frequency will be kept the same, thereby keeping the phase the same in the most critical frequency range of the feedback loop. The output voltage settling behavior is related to the stability of the closed-loop system and will demonstrate the actual overall supply performance.

Automotive Considerations: Plugging Into the Cigarette Lighter

As battery-powered devices go, there is a natural interest in plugging into the cigarette lighter in order to conserve or even recharge battery packs during operation. But before you connect, be advised: you are plugging into the supply from hell. The main battery line in an auto is the source of a number of nasty potential transients, including load dump, reverse battery and double battery.

Load dump is the result of a loose battery cable. When the cable breaks connection, the field collapse in the alternator can cause a positive spike as high as 60V which takes several hundred milliseconds to decay. Reverse battery is just what it says, while double battery is a consequence of

tow-truck operators finding that a 24V jump start cranks cold engines faster than 12V.

The network shown in Figure 7 is the most straight forward approach to protect a DC/DC converter from the ravages of an automotive battery line. The series diode prevents current from flowing during reverse battery, while the transient suppressor clamps the input voltage during load dump. Note that the transient suppressor should not conduct during double-battery operation, but must still clamp the input voltage below breakdown of the converter. Although the LTC1735-1 has a maximum input voltage of 36V, most applications will be limited to 30V by the MOSFET BV_{DSS} .

Figure 7. Plugging Into the Cigarette Lighter

Design Example

As a design example, assume $V_{IN} = 12\text{V}$ (nominal), $V_{IN} = 22\text{V}$ (max), $V_{OUT} = 1.5\text{V}$, $I_{MAX} = 12\text{A}$ and $f = 300\text{kHz}$, R_{SENSE} and C_{OSC} can immediately be calculated:

$$R_{SENSE} = 50\text{mV}/12\text{A} = 0.042\Omega$$

$$C_{OSC} = 1.61(10^7)/(300\text{kHz}) - 11\text{pF} = 43\text{pF}$$

Assume a $1.2\mu\text{H}$ inductor and check the actual value of the ripple current. The following equation is used :

$$\Delta I_L = \frac{V_{OUT}}{(f)(L)} \left(1 - \frac{V_{OUT}}{V_{IN}} \right)$$

The highest value of the ripple current occurs at the maximum input and output voltages:

$$\Delta I_L = \frac{1.5\text{V}}{300\text{kHz}(1.2\mu\text{H})} \left(1 - \frac{1.5\text{V}}{22\text{V}} \right) = 3.9\text{A}$$

APPLICATIONS INFORMATION

The maximum ripple current is 32% of maximum output current, which is about right.

Next, verify the minimum on-time of 200ns is not violated. The minimum on-time occurs at maximum V_{IN} and minimum V_{OUT} .

$$t_{ON(MIN)} = \frac{V_{OUT}}{V_{IN(MAX)}f} = \frac{1.5V}{22V(300kHz)} = 227ns$$

The power dissipation on the topside MOSFET can be easily estimated. Choosing a Fairchild FDS6612A results in; $R_{DS(ON)} = 0.03\Omega$, $C_{RSS} = 80pF$. At maximum input voltage with T (estimated) = 50°C:

$$\begin{aligned} P_{MAIN} &= \frac{1.5V}{22V} (12)^2 [1 + (0.005)(50^\circ C - 25^\circ C)] (0.03\Omega) \\ &\quad + 1.7(22V)^2 (12A)(80pF)(300kHz) \\ &= 568mW \end{aligned}$$

Because the duty cycle of the bottom MOSFET is much greater than the top, two larger MOSFETs must be paralleled. Choosing Fairchild FDS6680A MOSFETs yields a parallel $R_{DS(ON)}$ of 0.0065 Ω . The total power dissipation for both bottom MOSFETs, again assuming $T = 50^\circ C$, is:

$$\begin{aligned} P_{SYNC} &= \frac{22V - 1.5V}{22V} (12A)^2 (1.1)(0.0065\Omega) \\ &= 959mW \end{aligned}$$

Thanks to current foldback, the bottom MOSFET dissipation in short circuit will be less than under full-load conditions.

C_{IN} is chosen for an RMS current rating of at least 6A at temperature. C_{OUT} is chosen with an ESR of 0.01 Ω for low output ripple. The output ripple in continuous mode will be highest at the maximum input voltage. The output voltage ripple due to ESR is approximately:

$$V_{ORIPPLE} = R_{ESR}(\Delta I_L) = 0.01\Omega(3.9A) = 39mV_{P-P}$$

PC Board Layout Checklist

When laying out the printed circuit board, the following checklist should be used to ensure proper operation of the LTC1735-1. These items are also illustrated graphically in the layout diagram of Figure 8. Check the following in your layout:

1. Are the signal and power grounds segregated? The LTC1735-1 signal ground pin must return to the (-) plate of C_{OUT} . The power ground connects to the source of the bottom N-channel MOSFET, anode of the Schottky diode and (-) plate of C_{IN} , which should have as short lead lengths as possible.
2. Does the V_{OSENSE} pin connect directly to the feedback resistors? The resistive divider R1, R2 must be connected between the (+) plate of C_{OUT} and signal ground. The 47pF capacitor from V_{OSENSE} to SGND should be as close as possible to the LTC1735-1.
3. Are the SENSE⁺ and SENSE⁻ leads routed together with minimum PC trace spacing? The filter capacitor between SENSE⁺ and SENSE⁻ should be as close as possible to the LTC1735-1.
4. Does the (+) plate of C_{IN} connect to the drain of the topside MOSFET(s) as closely as possible? This capacitor provides the AC current to the MOSFET(s).
5. Is the INTV_{CC} decoupling capacitor connected closely between INTV_{CC} and the power ground pin? This capacitor carries the MOSFET driver peak currents. An additional 1 μ F ceramic placed immediately next to the INTV_{CC} and PGND pins can help improve noise performance.
6. Keep the switching node (SW), Top Gate node (TG), and Boost node (BOOST) away from sensitive small-signal nodes, especially from the voltage and current sensing feedback pins. All of these nodes have very large and fast moving signals and therefore should be kept on the "output side" (Pins 9 to 16) of the LTC1735-1 and occupy minimum PC trace area.

APPLICATIONS INFORMATION

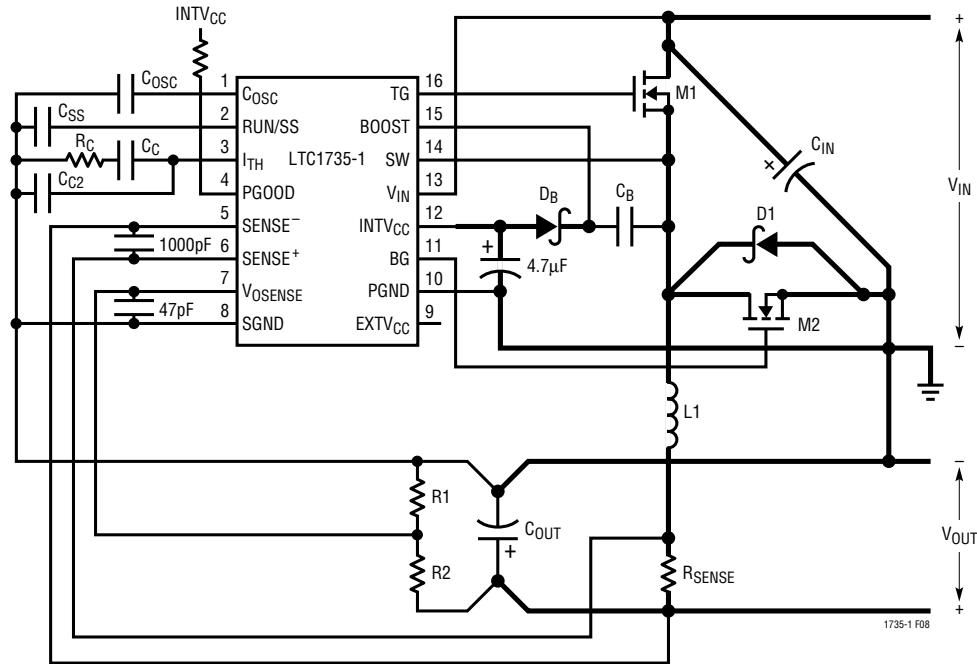

Figure 8. LTC1735-1 Layout Diagram

PACKAGE DESCRIPTION

Dimensions in inches (millimeters) unless otherwise noted.

GN Package 16-Lead Plastic SSOP (Narrow 0.150) (LTC DWG # 05-08-1641)

* DIMENSION DOES NOT INCLUDE MOLD FLASH. MOLD FLASH SHALL NOT EXCEED 0.006" (0.152mm) PER SIDE
 ** DIMENSION DOES NOT INCLUDE INTERLEAD FLASH. INTERLEAD FLASH SHALL NOT EXCEED 0.010" (0.254mm) PER SIDE

S Package 16-Lead Plastic Small Outline (Narrow 0.150) (LTC DWG # 05-08-1610)

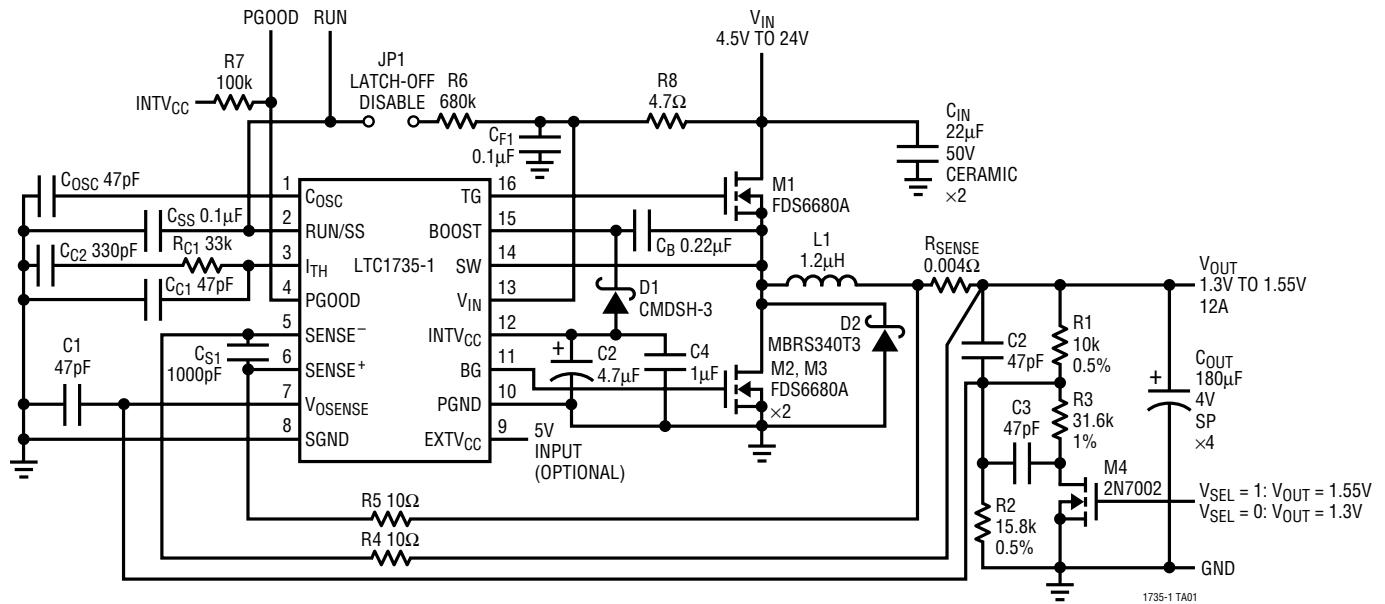

* DIMENSION DOES NOT INCLUDE MOLD FLASH. MOLD FLASH SHALL NOT EXCEED 0.006" (0.152mm) PER SIDE
 ** DIMENSION DOES NOT INCLUDE INTERLEAD FLASH. INTERLEAD FLASH SHALL NOT EXCEED 0.010" (0.254mm) PER SIDE

TYPICAL APPLICATION

High Efficiency Dynamic Output Voltage Selectable CPU Power Supply
