# Low Voltage PLL Clock Driver

The MPC9990 is a low voltage PLL clock driver designed for high speed clock generation and distribution in high performance computer, workstation and server applications. The clock driver accepts a LVPECL compatible clock signal and provides 10 low skew, differential HSTL<sup>1</sup> compatible outputs, one HSTL compatible output for system synchronization purposes and one HSTL compatible PLL feedback output. The device operates from a dual voltage supply: 3.3 V for the core logic and 1.8 V for the HSTL outputs. The fully integrated PLL supports an input frequency range of 75 to 287.5 MHz. The output frequencies are configurable.

- Supports high performance HSTL clock distribution systems
- Compatible to IA64 processor systems
- Fully Integrated PLL, differential design
- Core logic operates from 3.3 V power supply
- HSTL outputs operate from a 1.8 V supply
- Programmable frequency by output bank
- 10 HSTL compatible outputs (two banks)
- HSTL compatible PLL feedback output
- HSTL compatible synchronization output (QSYNC)
- Max. skew of 80 ps within output bank
- Zero-delay capability: max. SPO (tpd) window of 150 ps
- LVPECL compatible clock input, LVCMOS compatible control inputs
- Temperature range of 0 to +70°C

The MPC9990 provides output clock frequencies required for high-performance computer system optimization. The device drives up to 10 differential clock loads within the frequency range of 75 to 287.5 MHz. The 10 outputs are organized in 2 banks of 3 and 7 differential outputs. In the standard configuration the QFB output pair is connected to the FB input pair closing the PLL loop and enabling zero delay operation from the CLK input to the outputs. Bank B outputs are frequency and phase aligned to the CLK input, providing exact copies of the high-speed input signal. Bank A outputs are configured to operate at slower speeds driving the system bus devices. The output frequency ratio of bank A to bank B is adjustable (for available ratios, see "MPC9990 Application: CPU to System Bus Frequency Ratios" on page 2) for system optimization. In a computer application, bank B outputs generate the clock signals for the devices operating at the CPU frequency, while Bank A outputs are configured to drive the clock signals for the devices running at lower speeds (system clock). Four individual frequency ratios are available, providing a high degree of flexibility. The frequency ratios between CPU clock and system clock provided by the MPC9990 are listed in the table "Output configuration" on page 4.

The QSYNC output functionality is designed for system synchronization purpose. QSYNC is asserted at coincident rising edges of CPU (bank B and QFB signal) and slower system clock (bank A) outputs (see "QSYNC Phase Relation Diagram" on page 4), providing baseline timing in systems with fractional clocks. The QSYNC output is asserted for one QFB high pulse, centered on the rising QFB output.

**Figure 1. MPC9990 Application Example**

1. In order to minimize output-to-output skew, HSTL outputs of the MPC9990 are generated with an open emitter architecture. For output termination, see "HSTL Output Termination and AC Test Reference" on page 5.

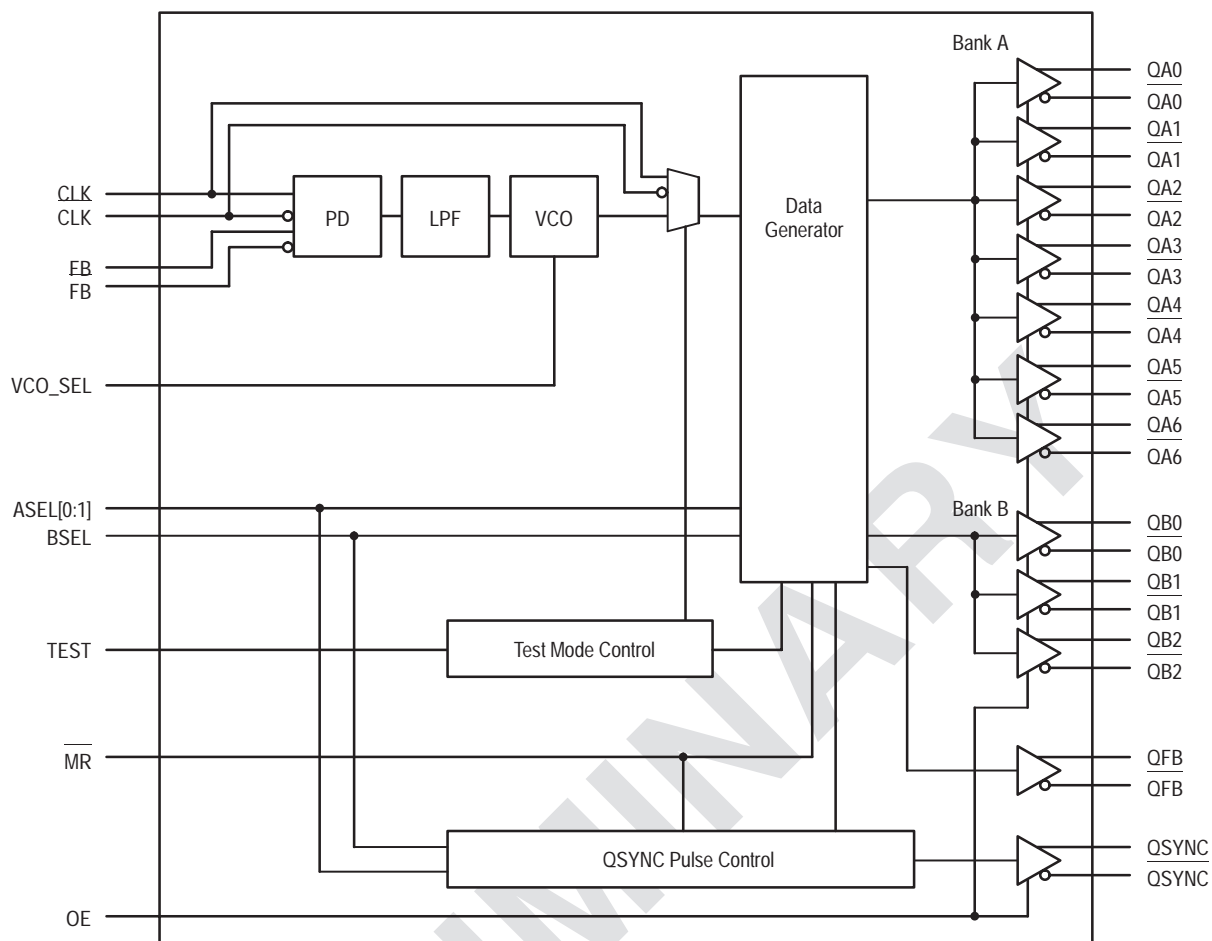

Figure 2. MPC9990 Logic Diagram

Table 1: MPC9990 Application: CPU to System Bus Frequency Ratios

QA to QB frequency ratio	1:1	1:2	3:4	4:5	
Output frequencies for CLK = 75 MHz (BSEL=1, VCO_SEL=1)					
QA output frequency	75	37.5	56.25	60	MHz
QB output frequency	75	75	75	75	MHz
Output frequencies for CLK = 100 MHz (BSEL=1, VCO_SEL=1)					
QA output frequency	100	50	75	80	MHz
QB output frequency	100	100	100	100	MHz
Output frequencies for CLK = 125 MHz (BSEL=1, VCO_SEL=1)					
QA output frequency	125	62.5	93.75	100	MHz
QB output frequency	125	125	125	125	MHz
Output frequencies for CLK = 150 MHz (BSEL=1, VCO_SEL=0)					
QA output frequency	150	75	112.5	120	MHz
QB output frequency	150	150	150	150	MHz
Output frequencies for CLK = 200 MHz (BSEL=1, VCO_SEL=0)					
QA output frequency	200	100	150	160	MHz
QB output frequency	200	200	200	200	MHz
Output frequencies for CLK = 250 MHz (BSEL=1, VCO_SEL=0)					
QA output frequency	250	125	187.5	200	MHz
QB output frequency	250	250	250	250	MHz

Table 2: Pin configuration

Pin	I/O	Type	Internal resistor	Description
CLK, $\overline{\text{CLK}}$	Input	LVPECL	CLK: pull-down, $\overline{\text{CLK}}$ : pull-up	Differential clock frequency input
FB, $\overline{\text{FB}}$	Input	HSTLL	FB: pull-down, $\overline{\text{FB}}$ : pull-up	Differential feedback input
QAn, $\overline{\text{QAn}}$	Output	HSTL		Bank A outputs
QBn, $\overline{\text{QBn}}$	Output	HSTL		Bank B outputs
QSYNC, $\overline{\text{QSYNC}}$	Output	HSTL		Synchronization output
QFB, $\overline{\text{QFB}}$	Output	HSTL		Differential feedback output
VCO_SEL	Input	LVC MOS	pull-down	Selection of operating frequency range
ASEL[0:1]	Input	LVC MOS	pull-down	Selection of bank A output frequency
BSEL	Input	LVC MOS	pull-down	Selection of bank B output frequency
TEST	Input	LVC MOS	pull-down	Selection of PLL operation or TEST mode (PLL bypass)
MR	Input	LVC MOS	pull-up	Master reset. Assertion of master reset required on startup
OE	Input	LVC MOS	pull-up	Output enable
VCCA		Power supply		Analog power supply, typical 3.3 V
VCC		Power supply		Core power supply, typical 3.3 V
VCCO		Power supply		Output power supply, typical 1.8 V
GND		Ground		Output, analog and core logic ground, 0V (VEE)

**Table 3: Output Frequency Relationship for an Example Configuration**

ASEL[0]	ASEL[1]	BSEL	f QAn	f QBn	f QFB	QSYNC
0	0	0	CLK	CLK	CLK	L
0	1	0	CLK ÷ 2	CLK ÷ 2	CLK	enabled
1	0	0	CLK x 3 ÷ 4	CLK x 3 ÷ 4	CLK	enabled
1	1	0	CLK x 4 ÷ 5	CLK x 4 ÷ 5	CLK	enabled
0	0	1	CLK	CLK	CLK	L
0	1	1	CLK ÷ 2	CLK	CLK	enabled
1	0	1	CLK x 3 ÷ 4	CLK	CLK	enabled
1	1	1	CLK x 4 ÷ 5	CLK	CLK	enabled

**Table 4: Function Table (Controls)**

Control Pin	0	1
TEST	PLL enabled	PLL bypassed (Static test mode)
$\overline{\text{MR}}$	Reset (Internal logic and PLL)	Normal operation mode
OE	Outputs disabled ( $Q_X = L, \overline{Q}_X = H$ ), except QFB, QFB	Outputs enabled
VCO_SEL	High frequency operation (VCO frequency range from 600 to 1150 MHz)	Low frequency operation (VCO frequency range from 300 to 575 MHz)

**Figure 4. QSYNC Phase Relation Diagram**

The MPC9990 QSYNC output is designed for system synchronization purpose. The output frequency relationship between the QA-bank and the QFB-output (see table 3) controls the status of QSYNC. The internal QSYNC pulse circuitry is enabled if the frequency relationship between the QA-banks and QFB is not an integer multiple of each other ( $f_{QA}:f_{QFB} = 1:2, 3:4$  and  $4:5$ ) (see table 3). QSYNC is asserted (logic high pulse) centered on coincident rising edges at the QA-bank outputs and QFB. The QSYNC output transitions at the falling edges of QFB (assertion at the last falling edge of QFB prior to the coincident edge event,

deassertion at the next falling edge of QFB). The QSYNC output pulse width is equal to period of the QFB output (see figure 4, also see the max. skew specification QFB to QSYNC).

If BSEL=1 and the PLL is frequency and phase locked, QSYNC output pulses occur centered on coincident edges between the QA-bank and QB-bank outputs (offset by the feedback path delay) due to the fixed relationship between CLK, QFB and QB bank outputs.

**Table 5: ABSOLUTE MAXIMUM RATINGS\***

Symbol	Characteristics	Min	Max	Units	Condition
V <sub>CCA</sub>	Analog power supply	-0.5	3.6	V

t <sub>Lock</sub>	PLL lock time			10			10			10	ms		

a. Refer to "HSTL Output Termination and AC Test Reference" for AC test conditions in Figure 6.

b. The input frequency for the output configurations are limited by the VCO frequency range and the feedback divider.

c.  $f_{OUT}$  at which output-to-output skew, V<sub>X</sub> and DC specification are still meet.  $f_{OUT}$  is primary a function of  $f_{IN}$  and the input-to-output frequency ratio (M:N).

d. Output skew within bank A outputs (QA0-QA6) and output skew within bank B outputs (QB0-QB2).

e. Output skew within all outputs (QA0-QA6, QB0-QB2) running at the same output frequency.

f. Output skew within all outputs (QA0-QA6, QB0-QB2) running at any output frequency.

g. V<sub>pp</sub> specifies the minimum input differential voltage required for switching.

## APPLICATIONS INFORMATION

## Using the MPC9990 in zero-delay applications

Nested clock trees are typical applications for the MPC9990 Designs using the MPC9990 as PLL fanout buffer with zero insertion delay will show significantly lower clock skew than clock distributions developed from static fanout buffers. The external feedback option of the MPC9990 clock driver allows for its use as a zero delay buffer. By using the differential QFB output pair as a feedback to the PLL the propagation delay through the device is virtually eliminated. The PLL aligns the feedback clock output edge with the clock input reference edge resulting a near zero delay through the device. The maximum insertion delay of the device in zero-delay applications is measured between the reference clock input (CLK) and any output. This effective delay consists of the static phase offset (SPO), I/O jitter (phase or long-term jitter), feedback path delay and the output-to-output skew error relative to the feedback output.

## Calculation of part-to-part skew

The MPC9990 zero delay buffer supports applications where critical clock signal timing can be maintained across several devices. If the reference clock inputs of two or more MPC9990 are connected together, the maximum overall timing uncertainty from the common CLK input to any output is:

$$t_{SK(PP)} = t_{(\emptyset)} + t_{SK(O)} + t_{PD,LINE(FB)} + t_{JIT(PER)} + t_{JIT(\emptyset)} \cdot CF$$

This maximum timing uncertainty consist of 4 components: static phase offset (SPO), output skew, feedback board trace delay and I/O phase and period jitter. The output skew ( $t_{SK(O)}$ ) specification of the MPC9990 is different for single or for dual frequency bank configurations. :

Complementary signals are not shown. Signal references level is the differential voltage crosspoint  $V_x$

Figure 7. MPC9990 max. device-to-device skew

Due to the statistical nature of I/O jitter a rms value ( $1\sigma$ ) is specified. I/O jitter numbers for other confidence factors (CF) can be derived from Table 8.

Table 8: Confidence Factor CF

CF	Probability of clock edge within the distribution
$\pm 1\sigma$	0.68268948
$\pm 2\sigma$	0.95449988
$\pm 3\sigma$	0.99730007
$\pm 4\sigma$	0.99993663
$\pm 5\sigma$	0.99999943
$\pm 6\sigma$	0.99999999

The feedback trace delay is determined by the board layout and can be used to fine-tune the effective delay through each device. In the following example calculation a I/O jitter confidence factor of 99.7% ( $\pm 3\sigma$ ) and single frequency configuration is assumed, resulting in a worst case timing uncertainty from input to any output of -495 ps to +245 ps relative to CLK.

$$t_{SK(PP)} = [-200ps...-50ps] + [-100ps...100ps] + [-75ps...75ps] + [(30ps \cdot -3)...(30ps \cdot 3)] + t_{PD,LINE(FB)}$$

$$t_{SK(PP)} = [-495ps...+245ps] + t_{PD,LINE(FB)}$$

Due to the frequency dependence of the I/O jitter, Figure 8. "Max. I/O Jitter versus frequency" can be used for a more precise timing performance analysis. The number for the I/O jitter at a specific frequency can be substituted for the more general datasheet specification number:

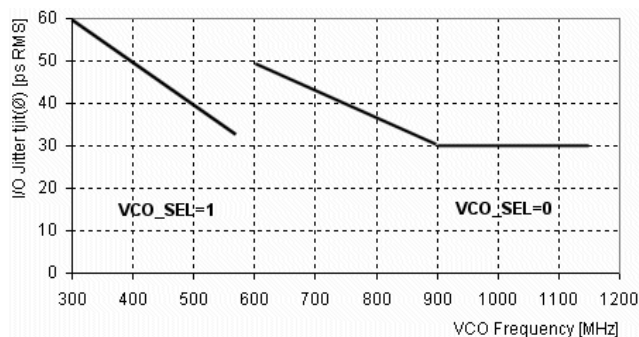

Figure 8. Max. I/O Jitter versus frequency

### Power Supply Filtering

The MPC9990 is a mixed analog/digital product. Its analog circuitry is naturally susceptible to random noise, especially if this noise is seen on the power supply. Random noise on the  $V_{CCA}$  power supply impacts the device AC characteristics, for instance I/O jitter. The MPC9990 provides separate power supplies for the output buffers ( $V_{CCO}$ ) and the phase-locked loop ( $V_{CCA}$ ) of the device.

Place  $V_{CCA}$  filter and  $V_{CCO}$ ,  $V_{CC}$  bypass capacitors as close as possible to the device

**Figure 9. Recommended Power Supply Filter**

The purpose of this design technique is to isolate the high switching noise digital outputs from the relatively sensitive internal analog phase-locked loop. In a digital system environment where it is difficult to minimize noise on the power supplies a second level of isolation may be required. A simple but effective form of isolation is a power supply filter on the  $V_{CCA}$  pin for the MPC9990. Figure 9. illustrates a recommended power supply low-pass frequency filter scheme. The MPC9990 VCO frequency and phase stability is most susceptible to noise with spectral content in the 300 kHz to 3 MHz range. Therefore the filter should be designed to target this range. The key parameter that needs to be met in the final filter design is the DC voltage drop across the series filter resistor  $R_F$ . The maximum voltage drop on  $V_{CCA}$  that can be tolerated is 135 mV with respect to  $V_{CC} = 3.3V \pm 5\%$ , resulting in a lowest allowable supply voltage for  $V_{CCA}$  equal to 2.835 V.

From the data sheet the  $I_{CCA}$  current (the current sourced through the  $V_{CCA}$  pin) is typically 11 mA (15 mA maximum), assuming that the minimum of 3.0V ( $V_{CC}=3.3V-5\%-0.135V$ ) must be maintained on the  $V_{CCA}$  pin. The resistor  $R_F$  shown in Figure 9. "Recommended Power Supply Filter" should

have a maximum resistance of  $9 \Omega$  to meet the voltage drop criteria. The minimum resistance for  $R_F$  and the filter capacitor  $C_F$  are defined by the required filter characteristics: the RC filter should provide an attenuation greater 40 dB for noise whose spectral content is above 300 kHz. In the example RC filter shown in Figure 9. "Recommended Power Supply Filter", the filter cut-off frequency is 16.3 kHz and the noise attenuation at 300 kHz is approximately 42 dB.

As the noise frequency crosses the series resonant point of an individual capacitor its overall impedance begins to look inductive and thus increases with increasing frequency. The parallel capacitor combination shown ( $6.8 \mu F \parallel 10 \text{ nF}$ ) ensures that a low impedance path to ground exists for frequencies well above the bandwidth of the PLL. Although the MPC9990 has several design features to minimize the susceptibility to power supply noise (isolated power and grounds, internal voltage regulation and fully differential PLL) there still may be applications in which overall performance is being degraded due to system power supply noise. The power supply filter schemes discussed in this section should be adequate to eliminate power supply noise related problems in most designs.

### Recommended Power-up Sequence

The MPC9990 does not require any special supply ramp sequence in case the system provides all supply voltages (3.3V and 1.8V) at the same time. The reference clock signal (CLK, CLK) can be applied any time during or after the power up sequence if  $V_{IN}$  is smaller or equal  $V_{CC}$  during the voltage transition. Following are guidelines for the MPC9990 power-up sequence in case the 3.3V and 1.8V voltage supply cannot be applied at the same time:

- HSTL output supply voltage  $V_{CCO}$  must be powered up to the specified voltage range before or at the same time as  $V_{CC}$ .  $V_{CCA}$  can be powered up before, at the same time or after  $V_{CC}$  and  $V_{CCO}$ .
- At the time the power supplies are powered up, the device should be reset ( $MR=0$ ).
- Apply the clock input signals to the PLL (CLK, CLK) after all power supplies are stable. Then, MR can be deasserted ( $MR=1$ ). This will release the internal PLL which will attempt to lock.
- The time from MR deassertion to PLL lock will be specified by the PLL lock time  $t_{Lock}$ . After the PLL achieved lock, the AC characteristics are valid.
- Outputs can be enabled by OE any time. QFB is not affected by OE and the PLL can achieve lock even if OE is tied high (OE = 1, disable).

### Calculating the Power Consumption

The total power dissipated in the MPC9990 ( $P_{TOT}$ ) can be represented by this formula:

$$P_{TOT} = P_{CORE} + (N \cdot P_{OUTPUT})$$

where  $P_{CORE}$  is the core and PLL power consumption ( $V_{CC}$  and  $V_{CCA}$  pins),  $P_{OUTPUT}$  is the power consumption of the output drivers ( $V_{CCO}$  pins) and  $N$  is the number of terminated outputs:

$$P_{CORE} = V_{CC} \cdot I_{CC}$$

$$P_{OUTPUT} = (V_{CCO} - V_{OUT}) \cdot [(V_X - V_{TT}) \div R_{TERM}]$$

$I_{CC}$  is the current consumption of the core including the current consumption of the PLL.  $V_X$  represents the average output voltage for a 50% duty cycle output signal.  $V_X$  and  $I_{CC}$  can be obtained from the specification values.  $V_{CC}$ ,  $V_{CCO}$ , and the termination resistor  $R_{TERM}$  are application-dependent.

**Table 9: Example Calculation**

Term	Value (worst case)	Value (typical case)
$V_{CC}$	3.3V+5%	3.3V
$I_{CCA}$	180 mA	141 mA
$P_{CORE}$	624 mW	465 mW
$V_{CCO}$	2.1V	1.8V
$V_{OUT}^b$	0.68V	0.8V
$V_X$	0.9V	0.8V
$V_{TT}$	0V	0V
$R_{TERM}$	50 $\Omega$	50 $\Omega$
$P_{OUTPUT}$	25.5 mW	16 mW
$N$	24	24
$P_{TOT}$	1237 mW	849 mW

- $I_{CC}$  already includes  $I_{CCA}$ .
- The value for  $V_{OUT}$  is average output voltage assuming the duty cycle of the output is approx. 50%.

The pin-to-pin skew is defined as the worst case difference in propagation delay between any two similar delay path within a single device ( $t_{SK(O)}$ ) or within a single output bank ( $t_{SK(OB)}$ )

**Figure 10. Output-to-output Skew  $t_{SK(O)}$ ,  $t_{SK(OB)}$**

**Figure 11. Propagation delay ( $t_{\phi}$ , static phase offset, SPO) test reference**

The time from the PLL controlled edge to the non controlled edge, divided by the time between PLL controlled edges, expressed as a percentage

**Figure 12. Output Duty Cycle (DC)**

The deviation in  $t_0$  for a controlled edge with respect to a  $t_0$  mean in a random sample of cycles, measured at the FB signal (only true signal shown)

**Figure 13. I/O Jitter**

The variation in cycle time of a signal between adjacent cycles, over a random sample of adjacent cycle pairs, measured at an output (only true signal shown)

**Figure 14. Cycle-to-cycle Jitter**

The deviation in cycle time of a signal with respect to the ideal period over a random sample of cycles (only true signal shown)

**Figure 15. Period Jitter**

**Figure 16. Output Transition Time Test Reference**

OUTLINE DIMENSIONS

FA SUFFIX  
LQFP PACKAGE  
CASE 932-03  
ISSUE F

- NOTES:
1. DIMENSIONING AND TOLERANCING PER ASME Y14.5M, 1994.
  2. CONTROLLING DIMENSION: MILLIMETER.
  3. DATUM PLANE AB IS LOCATED AT BOTTOM OF LEAD AND IS COINCIDENT WITH THE LEAD WHERE THE LEAD EXITS THE PLASTIC BODY AT THE BOTTOM OF THE PARTING LINE.
  4. DATUMS T, U, AND Z TO BE DETERMINED AT DATUM PLANE AB.
  5. DIMENSIONS S AND V TO BE DETERMINED AT SEATING PLANE AC.
  6. DIMENSIONS A AND B DO NOT INCLUDE MOLD PROTRUSION. ALLOWABLE PROTRUSION IS 0.250 PER SIDE. DIMENSIONS A AND B DO INCLUDE MOLD MISMATCH AND ARE DETERMINED AT DATUM PLANE AB.
  7. DIMENSION D DOES NOT INCLUDE DAMBAR PROTRUSION. DAMBAR PROTRUSION SHALL NOT CAUSE THE D DIMENSION TO EXCEED 0.350.
  8. MINIMUM SOLDER PLATE THICKNESS SHALL BE 0.0076.
  9. EXACT SHAPE OF EACH CORNER IS OPTIONAL.

MILLIMETERS		
DIM	MIN	MAX
A	7.000 BSC	
A1	3.500 BSC	
B	7.000 BSC	
B1	3.500 BSC	
C	1.400	1.600
D	0.170	0.270
