

Dual Bootstrapped 12 V MOSFET Driver with Output Disable

ADP3118

FEATURES

- Optimized for low gate charge MOSFETs
- All-in-one synchronous buck driver
- Bootstrapped high-side drive
- One PWM signal generates both drives
- Anticross-conduction protection circuitry
- Output disable control turns off both MOSFETs to float output per Intel VRM 10
- Meets CPU VR requirement when used with Analog Devices, Inc. Flex-Mode¹ controller

APPLICATIONS

- Multiphase desktop CPU supplies
- Single-supply synchronous buck converters

GENERAL DESCRIPTION

The ADP3118 is a dual, high voltage MOSFET driver optimized for driving two N-channel MOSFETs, which are the two switches in a nonisolated synchronous buck power converter. Each of the drivers is capable of driving a 3000 pF load with a 25 ns propagation delay and a 25 ns transition time. One of the drivers can be bootstrapped and is designed to handle the high voltage slew rate associated with floating high-side gate drivers. The ADP3118 includes overlapping drive protection to prevent shoot-through current in the external MOSFETs.

The \overline{OD} pin shuts off both the high-side and the low-side MOSFETs to prevent rapid output capacitor discharge during system shutdown.

The ADP3118 is specified over the commercial temperature range of 0°C to 85°C and is available in 8-lead SOIC and 8-lead LFCSP packages.

¹ For LFCSP_VD, θ_{JA} is measured per JEDEC STD with the exposed pad soldered to PCB.

Stresses above those listed under Absolute Maximum Ratings may cause permanent damage to the device. This is a stress rating only; functional operation of the device at these or any other conditions above those indicated in the operational section of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

ESD CAUTION

ESD (electrostatic discharge) sensitive device. Charged devices and circuit boards can discharge without detection. Although this product features patented or proprietary protection circuitry, damage may occur on devices subjected to high energy ESD. Therefore, proper ESD precautions should be taken to avoid performance degradation or loss of functionality.

PIN CONFIGURATION AND FUNCTION DESCRIPTIONS

Figure 2. 8-Lead SOIC Pin Configuration

Table 3. Pin Function Descriptions

| Pin No. | Mnemonic | Description |
|---------|------------------------|---|
| 1 | BST | Upper MOSFET Floating Bootstrap Supply. A capacitor connected between the BST and SW pins holds this bootstrapped voltage for the high-side MOSFET as it is switched. |
| 2 | IN | Logic Level PWM Input. This pin has primary control of the driver outputs. In normal operation, pulling this pin low turns on the low-side driver; pulling it high turns on the high-side driver. |
| 3 | $\overline{\text{OD}}$ | Output Disable. When low, this pin disables normal operation, forcing DRVH and DRVL low. |
| 4 | VCC | Input Supply. This pin should be bypassed to PGND with an $\sim 1 \mu\text{F}$ ceramic capacitor. |
| 5 | DRVL | Synchronous Rectifier Drive. Output drive for the lower (synchronous rectifier) MOSFET. |
| 6 | PGND | Power Ground. Should be closely connected to the source of the lower MOSFET. |
| 7 | SW | This pin is connected to the buck-switching node, close to the upper MOSFET's source. It is the floating return for the upper MOSFET drive signal. It is also used to monitor the switched voltage to prevent turn-on of the lower MOSFET until the voltage is below $\sim 1 \text{ V}$. |
| 8 | DRVH | Buck Drive. Output drive for the upper (buck) MOSFET. |

Figure 12. Supply Current vs. Temperature

THEORY OF OPERATION

The ADP3118 is a dual-MOSFET driver optimized for driving two N-channel MOSFETs in a synchronous buck converter topology. A single PWM input signal is all that is required to properly drive the high-side and the low-side MOSFETs. Each driver is capable of driving a 3 nF load at speeds up to 500 kHz.

A more detailed description of the ADP3118 and its features follows (see Figure 1 for a block diagram).

LOW-SIDE DRIVER

The low-side driver is designed to drive a ground-referenced N-channel MOSFET. The bias to the low-side driver is internally connected to the VCC supply and PGND.

When the driver is enabled, the driver's output is 180° out of phase with the PWM input. When the ADP3118 is disabled, the low-side gate is held low.

HIGH-SIDE DRIVER

The high-side driver is designed to drive a floating N-channel MOSFET. The bias voltage for the high-side driver is developed by an external bootstrap supply circuit, which is connected between the BST and SW pins.

The bootstrap circuit comprises a diode, D1, and bootstrap capacitor, C_{BST1}. C_{BST2} and R_{BST} are included to reduce the high-side gate drive voltage and to limit the switch node slew rate (referred to as a Boot-Snap circuit, see the Application Information section for more details). When the ADP3118 is starting up, the SW pin is at ground, so the bootstrap capacitor charges up to VCC through D1. When the PWM input goes high, the high-side driver begins to turn on the high-side MOSFET, Q1, by pulling charge out of C_{BST1} and C_{BST2}. As Q1 turns on, the SW pin rises up to V_{IN}, forcing the BST pin to V_{IN} + V_{C(BST)}, which is enough gate-to-source voltage to hold Q1 on.

To complete the cycle, Q1 is switched off by pulling the gate down to the voltage at the SW pin. When the low-side MOSFET, Q2, turns on, the SW pin is pulled to ground. This allows the bootstrap capacitor to charge up to VCC again.

The high-side driver's output is in phase with the PWM input. When the driver is disabled, the high-side gate is held low.

OVERLAP PROTECTION CIRCUIT

The overlap protection circuit prevents both of the main power switches, Q1 and Q2, from being on at the same time. This is done to prevent shoot-through currents from flowing through both power switches and the associated losses that can occur during their on/off transitions. The overlap protection circuit accomplishes this by adaptively controlling the delay from the Q1 turn-off to the Q2 turn-on, and by internally setting the delay from the Q2 turn-off to the Q1 turn-on.

To prevent the overlap of the gate drives during the Q1 turn-off and the Q2 turn-on, the overlap circuit monitors the voltage at the SW pin. When the PWM input signal goes low, Q1 begins to turn off (after propagation delay). Before Q2 can turn on, the overlap protection circuit makes sure that SW has first gone high and then waits for the voltage at the SW pin to fall from V_{IN} to 1 V. Once the voltage on the SW pin falls to 1 V, Q2 begins turn-on. If the SW pin has not gone high first, the Q2 turn-on is delayed by a fixed 150 ns. By waiting for the voltage on the SW pin to reach 1 V or for the fixed delay time, the overlap protection circuit ensures that Q1 is off before Q2 turns on, regardless of variations in temperature, supply voltage, input pulse width, gate charge, and drive current. If SW does not go below 1 V after 190 ns, DRV1 turns on. This can occur if the current flowing in the output inductor is negative and is flowing through the high-side MOSFET body diode.

APPLICATION INFORMATION

SUPPLY CAPACITOR SELECTION

For the supply input (V_{CC}) of the ADP3118, a local bypass capacitor is recommended to reduce the noise and to supply some of the peak currents drawn. Use a 4.7 μF , low ESR capacitor. Multilayer ceramic chip capacitors (MLCC) provide the best combination of low ESR and small size. Keep the ceramic capacitor as close as possible to the ADP3118.

BOOTSTRAP CIRCUIT

The bootstrap circuit uses a charge storage capacitor (C_{BST}) and a diode, as shown in Figure 1. These components can be selected after the high-side MOSFET is chosen. The bootstrap capacitor must have a voltage rating that can handle twice the maximum supply voltage. A minimum 50 V rating is recommended. The capacitor values are determined by:

$$C_{BST1} + C_{BST2} = 10 \times \frac{Q_{GATE}}{V_{GATE}} \quad (1)$$

$$\frac{C_{BST1}}{C_{BST1} + C_{BST2}} = \frac{V_{GATE}}{V_{CC} - V_D} \quad (2)$$

where:

Q_{GATE} is the total gate charge of the high-side MOSFET at V_{GATE} .

V_{GATE} is the desired gate drive voltage (usually in the range of 5 V to 10 V, 7 V being typical).

V_D is the voltage drop across D1.

Rearranging Equation 1 and Equation 2 to solve for C_{BST1} yields

$$C_{BST1} = 10 \times \frac{Q_{GATE}}{V_{CC} - V_D}$$

C_{BST2} can then be found by rearranging Equation 1.

$$C_{BST2} = 10 \times \frac{Q_{GATE}}{V_{GATE}} - C_{BST1}$$

For example, an NTD60N02 has a total gate charge of about 12 nC at $V_{GATE} = 7$ V. Using $V_{CC} = 12$ V and $V_D = 1$ V, one finds $C_{BST1} = 12$ nF and $C_{BST2} = 6.8$ nF. Good quality ceramic capacitors should be used.

R_{BST} is used for slew-rate limiting to minimize the ringing at the switch node. It also provides peak current limiting through D1. An R_{BST} value of 1.5 Ω to 2.2 Ω is a good choice. The resistor needs to be able to handle at least 250 mW due to the peak currents that flow through it.

A small-signal diode can be used for the bootstrap diode due to the ample gate drive voltage supplied by V_{CC} . The bootstrap diode must have a minimum 15 V rating to withstand the maximum supply voltage. The average forward current can be estimated by

$$I_{F(AVG)} = Q_{GATE} \times f_{MAX} \quad (3)$$

where f_{MAX} is the maximum switching frequency of the controller.

The peak surge current rating should be calculated using

$$I_{F(PEAK)} = \frac{V_{CC} - V_D}{R_{BST}} \quad (4)$$

MOSFET SELECTION

When interfacing the ADP3118 to external MOSFETs, there are a few considerations that the designer should be aware of. These help to make a more robust design that minimizes stresses on both the driver and the MOSFETs. These stresses include exceeding the short-time duration voltage ratings on the driver pins as well as the external MOSFET.

It is also highly recommended to use a Boot-Snap circuit to improve the interaction of the driver with the characteristics of the MOSFETs. If a simple bootstrap arrangement is used, make sure to include a proper snubber network on the SW node.

HIGH-SIDE (CONTROL) MOSFETS

The high-side MOSFET is usually selected to be high speed to minimize switching losses (see the ADP3186 or ADP3188 data sheet for controller details). This usually implies a low gate resistance and low input capacitance/charge device. Yet, a significant source lead inductance can also exist. This depends mainly on the MOSFET package; it is best to contact the MOSFET vendor for this information.

The ADP3118 DRVH output impedance and the input resistance of the MOSFETs determine the rate of charge delivery to the gate's internal capacitance. This determines the speed at which the MOSFETs turn on and off. However, due to potentially large currents flowing in the MOSFETs at the on and off times (this current is usually larger at turn off due to ramping up of the output current in the output inductor), the source lead inductance generates a significant voltage when the high-side MOSFETs switch off. This creates a significant drain-source voltage spike across the internal die of the MOSFETs and can lead to a catastrophic avalanche. The mechanisms involved in this avalanche condition can be referenced in literature from the MOSFET suppliers.

The MOSFET vendor should provide a maximum voltage slew rate at a drain current rating such that this can be designed around. Once the designer has this specification, determine the maximum current you expect to see in the MOSFET. This can be done with the following equation:

$$I_{MAX} = I_{DC} (\text{per phase}) + (V_{CC} - V_{OUT}) \times \frac{D_{MAX}}{f_{MAX} \times L_{OUT}} \quad (5)$$

where:

D_{MAX} is determined for the VR controller being used with the driver. This current is divided as equally as possible between MOSFETs if more than one is used (assume a worst-case mismatch of 30% for design margin).

L_{OUT} is the output inductor value.

When producing a design, there is no exact method for calculating the dV/dt due to the parasitic effects in the external MOSFETs as well as the PCB. However, it can be measured to determine if it is safe. If it appears that the dV/dt is too fast, an optional gate resistor can be added between DRVH and the high-side MOSFETs. This resistor slows down the dV/dt , but it increases the switching losses in the high-side MOSFETs. The ADP3118 has been optimally designed with an internal drive impedance that works with most MOSFETs to switch them efficiently yet minimizes dV/dt . However, some high speed MOSFETs may require this external gate resistor depending on the currents being switched in the MOSFET.

LOW-SIDE (SYNCHRONOUS) MOSFETS

The low-side MOSFETs are usually selected to have a low on resistance to minimize conduction losses. This usually implies a large input gate capacitance and gate charge. The first concern is to make sure the power delivery from the ADP3118's DRVH does not exceed the thermal rating of the driver (see the ADP3186 or ADP3188 data sheet for controller details).

The next concern for the low-side MOSFETs is based on preventing them from inadvertently being switched on when the high-side MOSFET turns on. This occurs due to the drain-gate (Miller, also specified as C_{rss}) capacitance of the MOSFET. When the drain of the low-side MOSFET is switched to V_{CC} by the high-side turning on (at a rate of dV/dt), the internal gate of the low-side MOSFET is pulled up by an amount roughly equal to $V_{CC} \times (C_{rss}/C_{iss})$. It is important to make sure this does not put the MOSFET into conduction.

Another consideration is the nonoverlap circuitry of the ADP3118, which attempts to minimize the nonoverlap period. During the state of the high-side turning off to low-side turning on, the SW pin is monitored (as well as the conditions of SW prior to switching) to adequately prevent overlap.

However, during the low-side turn off to high-side turn on, the SW pin does not contain information for determining

the proper switching time, so the state of the DRVH pin is monitored to go below one sixth of V_{CC} . A delay is then added. Due to the Miller capacitance and internal delays of the low-side MOSFET gate, one must ensure that the Miller-to-input capacitance ratio is low enough and that the low-side MOSFET internal delays are not so large as to allow accidental turn on of the low-side when the high-side turns on.

Contact sales for an updated list of recommended low-side MOSFETs.

PC BOARD LAYOUT CONSIDERATIONS

Use the following general guidelines when designing printed circuit boards.

- Trace out the high current paths and use short, wide (>20 mil) traces to make these connections.
- Minimize trace inductance between DRVH and DRVH outputs and MOSFET gates.
- Connect the PGND pin of the ADP3118 as closely as possible to the source of the lower MOSFET.
- Locate the V_{CC} bypass capacitor as close as possible to the VCC and PGND pins.
- Use vias to other layers when possible to maximize thermal conduction away from the IC.

The circuit in Figure 15 shows how four drivers can be combined with the ADP3188 to form a total power conversion solution for generating $V_{CC(CORE)}$ for an Intel® CPU that is VRD 10.x-compliant.

Figure 14 shows an example of the typical land patterns based on the guidelines given previously. For more detailed layout guidelines for a complete CPU voltage regulator subsystem, refer to the Layout and Component Placement section of the ADP3188 data sheet.
