

DIGITAL HYBRID WITH THE Si305x DAAs

1. Introduction

This application note is a guide to understanding and implementing the digital hybrid feature found in Si305x DAA products. The Si305x contains an on-chip analog hybrid that performs the 2- to 4-wire conversion and near-end echo cancellation. This hybrid circuit is adjusted for each ac termination setting selected to achieve a minimum transhybrid balance of 20 dB. The Si305x also offers a digital filter for additional near-end echo cancellation to compensate for any line impedance mismatch. For each ac termination setting, the eight programmable hybrid registers (Registers 45-52) can be programmed with coefficients to increase the cancellation under real-world line conditions. This digital filter can produce 10 dB or greater of near-end echo cancellation in addition to the 20 dB from the analog hybrid circuitry.

1.1. Digital Hybrid Overview

Figure 1 describes the basic architecture of the digital hybrid. It is composed of an 8-tap FIR filter. "b0" through "b7" represent the filter coefficients in 2s complement form. The initial 4-sample bulk delay is used to compensate for the round trip delay through the line-side device. This architecture is designed to delay and filter the transmit signal to match the portion not cancelled by the analog hybrid.

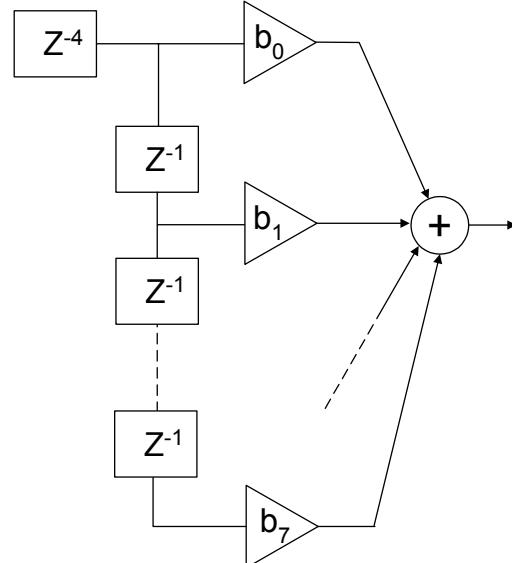

Figure 1. Digital Hybrid Structure

Figure 2 illustrates the basic signal flow of the DAA. The digital signal has been upsampled to 16 kHz at the digital hybrid stage. The transmit signal goes through a digital filter, digital-to-analog converter, and analog filter before going out on the line or being used in the analog hybrid circuitry. After the analog hybrid, the receive signal passes through an analog filter, analog-to-digital converter, and digital filter before going back into the digital hybrid. The analog hybrid path adds approximately four samples of delay to the signal. The digital hybrid structure matches this filter delay by delaying the digital samples by the same amount.

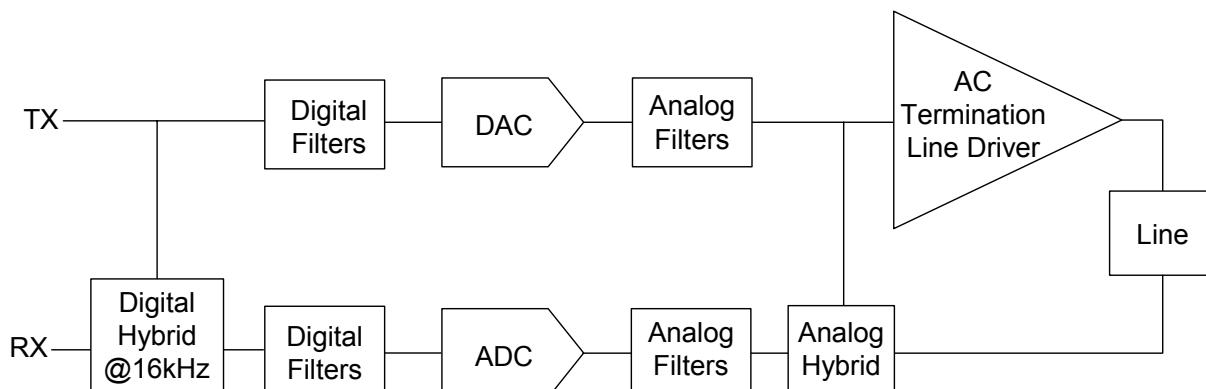

Figure 2. Signal Flow Diagram

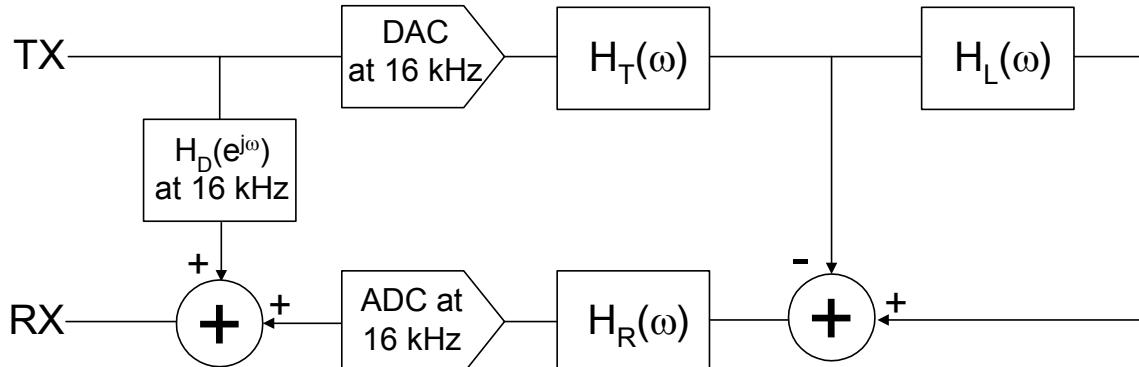

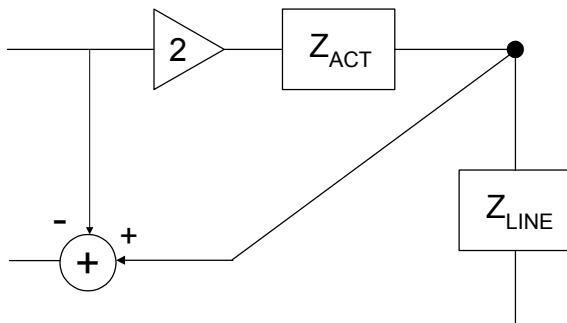

Figure 3. Model

A model of the DAA and the phone line is shown in Figure 3. In an ideal system, the analog hybrid yields perfect cancellation of the near-end echo from the transmit path. A mismatch between the ac termination and the load produces an echo that is not removed by the analog hybrid. To increase the near-end echo cancellation, the digital hybrid must equalize the disparity between the impedance mismatch of the ac termination and the line.

From the above model, the echo is equal to:

$$\begin{aligned}\text{echo} &= H_T(\omega) \times H_L(\omega) \times H_R(\omega) - H_T(\omega) \times H_R(\omega) \\ &= H_T(\omega) \times H_R(\omega)[H_L(\omega) - 1]\end{aligned}$$

$H_L(\omega)$ consists of the DAA's ac termination in combination with the impedance of the twisted pair transmission line terminated at the central office (CO) by a reference impedance. Figure 4 shows the analog hybrid circuitry and the $H_L(\omega)$ model expanded to include the ac termination and line.

Figure 4. $H_L(\omega)-1$ Model

Substituting for $H_L(\omega)$ in the equation results in:

$$H_L - 1 = 2 \times \frac{Z_{\text{Line}}}{Z_{\text{Line}} + Z_{\text{ACT}}} - 1 = \frac{Z_{\text{Line}} - Z_{\text{ACT}}}{Z_{\text{Line}} + Z_{\text{ACT}}}$$

If Z_{LINE} and Z_{ACT} are matched, the analog hybrid perfectly cancels the transmit signal.

Substituting this result into the echo equation yields:

$$\text{echo} = H_T(\omega) \times H_R(\omega) \left[\frac{Z_{\text{Line}} - Z_{\text{ACT}}}{Z_{\text{Line}} + Z_{\text{ACT}}} \right]$$

The model for the $H_T(\omega)$ and $H_R(\omega)$ plays a critical role in this calculation. The models are quite complex, and sampled data of the models are necessary to calculate the hybrid coefficients. Contact Silicon Labs to acquire the sampled data of the $H_T(\omega)$ and $H_R(\omega)$ models.

A group delay, which was not illustrated in the model, must also be taken into consideration. Internal DSP and filters cause this delay. Taking the group delay into account, the echo is equal to:

$$\text{echo} = H_T(\omega) \times H_R(\omega) \times [H_L(\omega) - 1] e^{\left(\frac{j2\pi}{16000} \times gd \right)}$$

where gd is the group delay.

The digital hybrid must cancel the echo by intentionally adding the negative of the echo. The $H_D(\omega)$ should be:

$$H_D(\omega) = -H_T(\omega) \times H_R(\omega) \times [H_L(\omega) - 1] e^{\left(\frac{j2\pi}{16000} \times gd \right)}$$

1.2. Digital Hybrid Calculation Tool

Silicon Labs has developed a useful graphical user interface tool (shown in Figure 5) that will assist in calculating the coefficients to use with the digital hybrid in the Si305x DAA product family. The tool allows the user to enter the reference termination of the central office (in an $R + R||C$ format) and the model for the phone line between the DAA and the central office. The line can be represented by one of the EIA models, shown in "Appendix C—EIA Line Models" on page 24, or as a specified length of wire. The software then executes the Matlab code found in "Appendix A—Sample MATLAB Code" on page 7, which graphically shows the expected trans-hybrid response of the digital hybrid and lists the best hybrid coefficients to use given the line characteristics.

Three graphs are shown in Figure 6. An echo graph is created by intentionally mismatching the $600\ \Omega$ ac termination with the TBR21 mode CO termination. The digital hybrid response is the 8-tap FIR filter response calculated using the sample code found in Appendix A. The cancelled graph is obtained by adding the echo and the digital hybrid response. The digital hybrid response looks very similar to an echo. Figure 7 shows the phase of the echo and the digital hybrid response. The phase of an echo and the digital hybrid have the opposite polarity. Figure 8 compares the rejection in dB with and without the digital hybrid. By properly using the digital hybrid, near-end echo cancellation has increased by approximately 20 dB.

To use the Digital Hybrid Calculation Tool, simply enter the ACIM value recommended in Table 13 of the Si3050 datasheet into the ACIM control. This value determines the impedance presented by the DAA to the line. It is governed by the region in which the application will be deployed. Next, enter values for R1 and R2 in ohms and C in farads into the appropriate controls. These values will represent the impedance presented by the central office to the line. This value is also governed by the region in which the application will be deployed. Also, select the line-side device used in the application in the pull-down box. Finally, select the line model to be used that will most closely model the line connecting the DAA to the central office. This is done by either picking a specific EIA line model or by specifying a wire gauge and length. Once this is complete, hitting the "CALCULATE" button will generate the coefficients that provide the best performance.

For example, if we assume that an application will be deployed within the U.S., we enter a 0 for the ACIM value. Also, the central office impedance in the US is $900\ \Omega$ in series with $2.16\ \mu F$. To enter this information in the GUI, we enter 900 for R1 and a fairly large value for R2, since it is not present. For this example, the value of $100,000\ \Omega$ was used. For the C value, we enter $2.16e-6$ since the expected units are farads. Also, for this example, we use an EIA model of 0. This means essentially no loop length, and the central office impedance is connected directly to the application. Now, the "CALCULATE" button is pressed, and the resulting coefficients, 0xF8, 0xF9, 0x03, 0xFE, 0xFE, 0x00, 0xFE, and 0x00, are generated.

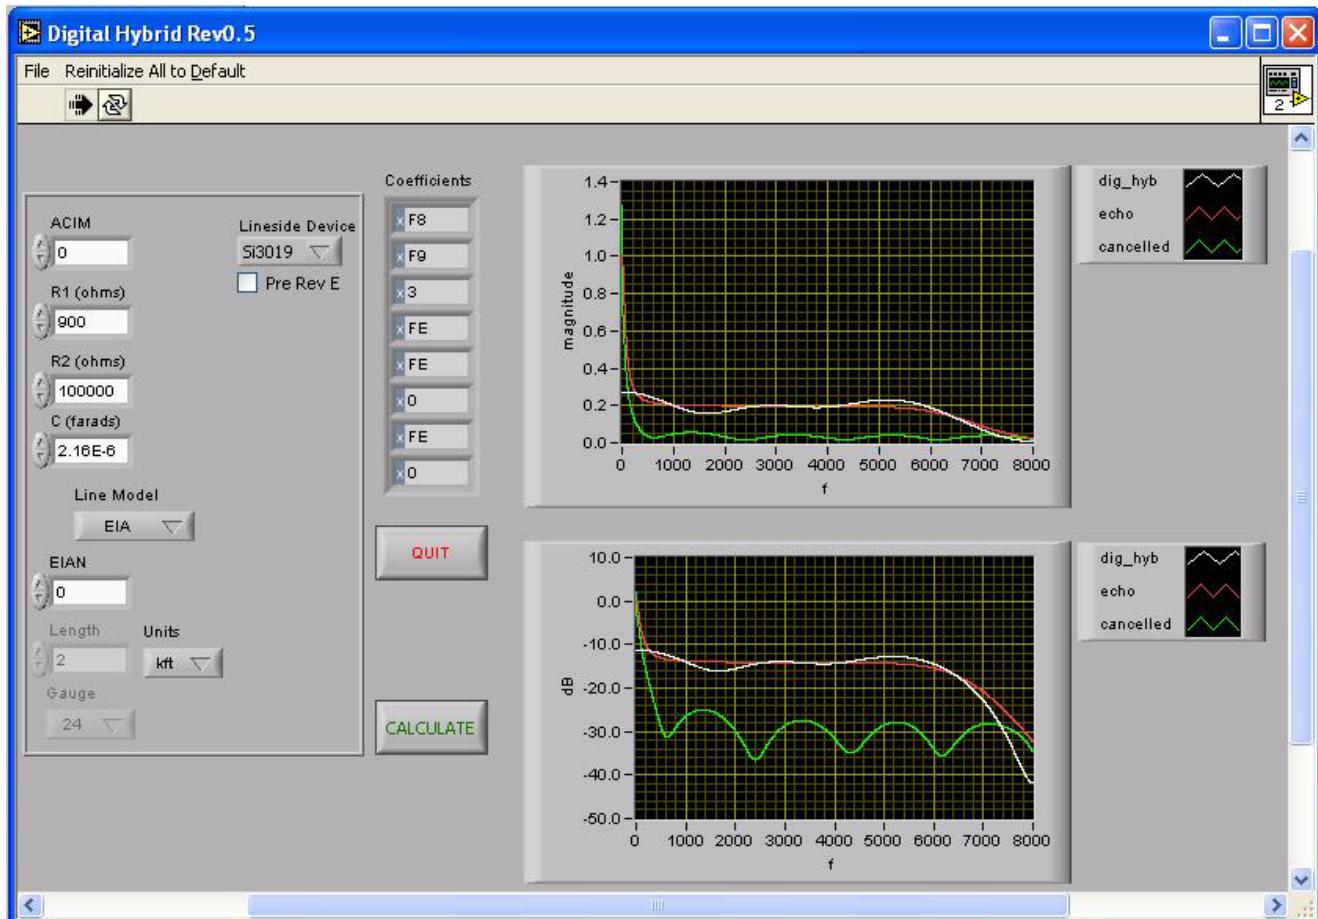

Figure 5. Digital Hybrid

1.3. Conclusion

The Si305x DAA product family is designed to increase the near-echo cancellation with an additional hybrid in the digital path operating at 16 kHz. Near-end echo is primarily caused by the mismatch between the ac termination and the CO termination. The transmit and receive signal path also affects the echo to a lesser extent. By introducing a filter that models the near-end echo 180 degrees out-of-phase to the receive path echo, the hybrid response can be improved. This improvement in the hybrid response results in greater cancellation of the transmit signal when the near-end echo and digital hybrid response are added together at the digital hybrid stage.

To generate the coefficients, the 8-tap FIR filter structure used in the digital hybrid must be taken into account. This digital filter structure requires the hybrid response to be represented in the z-domain.

"Appendix A—Sample MATLAB Code" contains sample MATLAB code to calculate the hybrid coefficients. This code should help in understanding the process of calculating the hybrid coefficients.

A hybrid coefficient lookup table can be found in "Appendix B—Hybrid Coefficient Lookup Tables" on page 10. These tables provide a set of coefficients to use for different line conditions.

APPENDIX B—HYBRID COEFFICIENT LOOKUP TABLES

Tables 1–14 (for Rev C and prior versions of the Si3019) and Tables 15–28 (for Rev E and later versions of the Si3019) provide fixed digital hybrid coefficients to best match the line load with specific EIA line models. For this calculation, the EIA line model was incorporated into the HL(w) model. The first column shows which line type was used to calculate the hybrid coefficient. The remaining columns display the hybrid coefficients (Registers 45–52).

APPENDIX C—EIA LINE MODELS

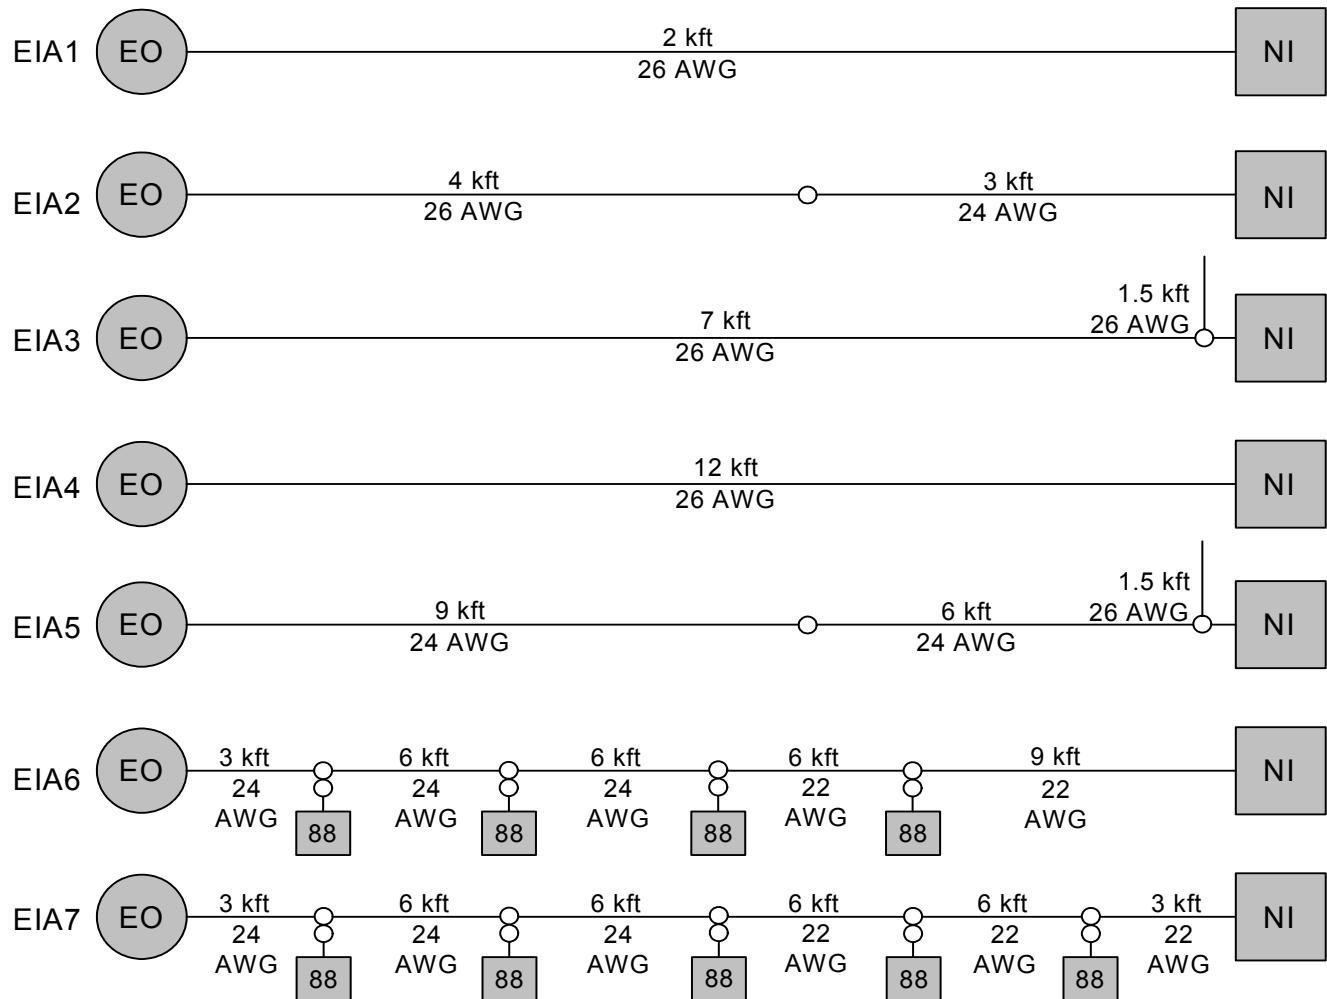

Figure 9. EIA Line Models

DOCUMENT CHANGE LIST

Revision 0.3 to Revision 0.4

- Added Figure 5 on page 4.
- Added " Appendix C—EIA Line Models" on page 24.

Revision 0.4 to Revision 0.5

- Updated Figure 5 on page 4.
- Added Tables 17–32 (information for Rev E and later versions of the Si3019).

Revision 0.5 to Revision 0.6

- Updated "1.2. Digital Hybrid Calculation Tool" on page 3.
- Updated Figure 5 on page 4.
- Updated " Appendix B—Hybrid Coefficient Lookup Tables" on page 10.
